DEDICATION

My whole thesis work is dedicated to my Parents, Brothers, Sister, Teachers & my
Friends who encouraged me and
all those who love me and whom I love.

ACKNOWLEDGEMENT

All praises for Almighty ALLAH, the most beneficial, the most merciful compassionate creator of the universe, Who blessed me with the knowledge and enabled me to complete this research work.

All respect to Holy Prophet Hazrat Muhammad (P.B.U.H) who appeared and blossomed as model for whole of humanity.

I specially acknowledge the help, the encouragement, endless love and prayers of my family specially my loving and caring Mother and Father, who have always been a source of inspiration and guidance for me all the way, whose valuable prayers, salutary advices and emboldening attitude kept my sprit alive to reach this milestone.

I am especially indebted to my thesis supervisor **Dr.Gulraiz Akhter** and all the respected teachers of department of Earth Sciences Q.A.U Islamabad for giving me an initiative to this study. Their inspiring guidance, dynamic supervision and constructive criticism enabled me to complete this thesis work. I am extremely thankful to my brothers, Mr.Manzoor Ahmad, Mr.Nawaz and Mr.Dilshad. I am also thankful to my respected seniors **Mr. Ajam Abbas** and **Mr.Junaid** for their moral support in thesis work

ABSTRACT

The Seismic lines 856-SGR-56 & 846-SGR-50 were given for study. To investigate the lateral and vertical variations of velocity within a layer average velocity and Iso-velocity graphs were prepared. Four reflectors and normal faults are marked.

To see reflectors positions and to study their nature, seismic time and depth sections were prepared which shows Horst & Grabon structures which may be favourable for hydrocarbon. Time and depth contour maps of Basal Sand are also prepared.

A descriptive analysis of Rock Physics using TD and RHOB Log Data of DHAMRAKHI#1 well has been made. Rock Physical Properties (e.g. P-wave Impedance, S-wave Impedance, Poisson Ratio, Bulk and Shear Modulus, etc) are calculated for a particular zone whose depth ranges from 2000m to 2900m. Actually this analysis is made to seek for the hydrocarbon potential zone using cross plots of different physical properties as mentioned above. These properties (P-wave Impedance, S-wave Impedance Bulk and Shear Modulus) were found high in sand ,that must be low in reservoir No reservoir zone was identified.

1.1 INTRODUCTION

The area of study is lying in Southern Indus Basin in Sindh province (Sanghar). Sanghar, is a small city roughly 35 miles (56 km) east-south-east of the city of Nawabshah and the same distance north of Mirpur Khas.

Map of Sanghar is shown in Fig:1.1. Two seismic lines 856-SGR-58 and 846-SGR-50 were provided by the department of Earth Sciences Quaid-I-Azam University Islamabad, in order to interpret the seismic sections along the given seismic lines.

a) LATITUDE OF THE AREA

Latitude of the area is $26^{\circ}, 19', 00''$ N to $26^{\circ}, 24', 00''$ N

b) LONGITUDE OF THE AREA

Longitude of the area is $69^{\circ}, 00', 00''$ E to $69^{\circ}, 05', 30''$ E

Fig :1.1 Map showing the location of area of interest (www.googlemaps.com)

1.2 BASE MAP

Base map is shown in Fig:1.2 on which primary data and interpretations can be plotted. A base map typically includes locations of concession boundaries, wells, seismic survey points and other cultural data such

as buildings and roads, with a geographic reference such as latitude and longitude or Universal Transverse Mercator (UTM), grid information.

Geologists use topographic maps as base maps for construction of surface geologic maps. Geophysicists typically use shot point maps, which show the orientations of seismic lines and the specific points at which seismic data were acquired, to display interpretations of seismic data.

1.5 METHODOLOGY AND OBJECTIVES

For study project area, iso velocity and average velocity graphs will be prepared using velocity functions given on the seismic section. Then horizons of interest will be marked based on their continuity and other interpretation techniques. Based on these marked horizons and above mentioned velocity functions, seismic time section will be prepared. Then a section in depth mode (depth section) will be prepared using the concerned velocities and other informations. Then using the tops of identified horizons on time and depth sections as basis, time and depth contour maps will be prepared for the horizons of interest.

This subsurface information will be used to create a tentative model to understand the trapping mechanisms of the study area.

Using DT and RHOB Log, I will determine the Seismic Parameters (P-Wave, S-Wave, Poisson's Ratio, Bulk Modulus, Shear Modulus, V_p/V_s Ratio and P-Wave and S-Wave Impedance) of lower Goru and by plotting Cross Plots, their application in hydrocarbon exploration.

Petrophysical Interpretation using NHPI and GR Log.

2.1 INTRODUCTION

The information about geology of an area plays very important role for a precise interpretation of seismic data. This chapter deals with a brief description of the tectonic setting, structural geology and stratigraphy of the study area (Sanghar) and adjoining areas, Lower Indus Basin. Petroleum significance of the area is also incorporated. The interpretation of seismic data in geological terms is the objective and end product of a seismic work. To investigate the geology of an area generally two types of information's are necessary:

- The Structural Information.
- The Stratigraphic Information

The structural information involves the knowledge about the geological structures (i.e. faults, folds etc) present in that area and The Stratigraphic Information tells us about different geological formations present there and the unconformities those lie between them.

Seismic data interpretation is based on the stratigraphy and structure geology of the area therefore it is important to have information about the geologic aspects of the area. The observations made in the present study have also been incorporated in the chapter.

2.2 REGIONAL GEOLOGICAL SETTING

The Indian Ocean and the Himalayas, two of the most pronounced global features surrounded the Indo-Pakistan subcontinent have a common origin. Both are the product of the geodynamic processes of sea-floor spreading, continental drift and collision tectonics. A plate of the earth's crust carrying the Indo-Pakistan landmass rifted away from the super continent Gondwanaland followed by the extensive sea-floor spreading and the opening up of the Indian Ocean. Propelled by the geodynamic forces the Indian plate traveled 5000 Km northward and eventually collided with Eurasia. The subduction of the northern margin of the Indian plate finally closed the Neotythes and the Indian Ocean assumed its present widespread expanse. This collision formed the Himalayas and the adjacent mountain ranges.

Pakistan has been divided into two broad geological zones, which are the;

- Gondwanaland Domain
- Tethyan Domain

Pakistan is unique in as much as it is located at the junction of these two diverse domains. The southern part of Pakistan belongs to Gondwanian Domain and is sustained by the Indo-Pakistan Crustal Plate. The northern most and western region of Pakistan fall in Tethyan Domain and present a complicated geology.

2.3 NORTHWARD DRIFT OF INDIAN PLATE AND ITS COLLISION WITH EURASIAN PLATE

The Indo-Pakistan subcontinent separated from the Gondwana motherland about 130 million years ago Johnson, et al., (1982).

It has been estimated that between 130 my. and 80 my. India moved northward at a rate of 3 to 5 cm/year Jhonson, et al. (1976). From 80 my. ago India moved at an average rate of about 16 cm/year relative to Australia and Antarctica. According to Patriat and Achache (1984), before anomaly 22 (50 my.) this rate of movement varied between 15 and 25 cm/year.

The Neotethys had begun to shrink by the time Indian began its northward drift around 130 my. ago. Intra-oceanic subduction generated a series of volcanic arcs (Kohistan-Ladakh, Nuristan, Kandhar) during the Cretaceous. This arc was intruded by 102 Ma precollision granitoids Treloar, et al. (1993) followed by the intra-arc rifting and magmatism. Arc magmatism covered a life-span of about 40 Ma after which the back-arc basin closed and Kohistan-Ladakh arc collided with Eurasia along the southern margin of the Karakoram plate.

The abrupt slowing down of Indian's northward movement between 55 and 50 my. ago is attributed to this collision. The abrupt slowing down of Indian from 18-19.5 cm/year to 4.5 cm/year occurred at 55+Ma. A combined India-Australia plate started moving away from Antarctica. Motion ceased along the former plate boundary (the Ninety East Ridge), and the Proto-Owen fracture no longer remained at transform fault, though it was reactivated later, about 20 Ma ago.

Since 55 Ma ago Indian plate has steadily rotated counterclockwise. Coupled with Arabian's separation from Africa about 20 Ma ago, this rotation caused convergence in Balochistan, closure of some the some smaller basins (Scistan, Katawaz), collision various crustal blocks in Iran-Afghanistan region and formation of the Balochistan fold-and-thrust belt. The India Eurasia collision produced the spectacular along uplifted and deformed 2,500 Km long Indo-Pakistan plate margin (Kazmi and Jan, 1997).

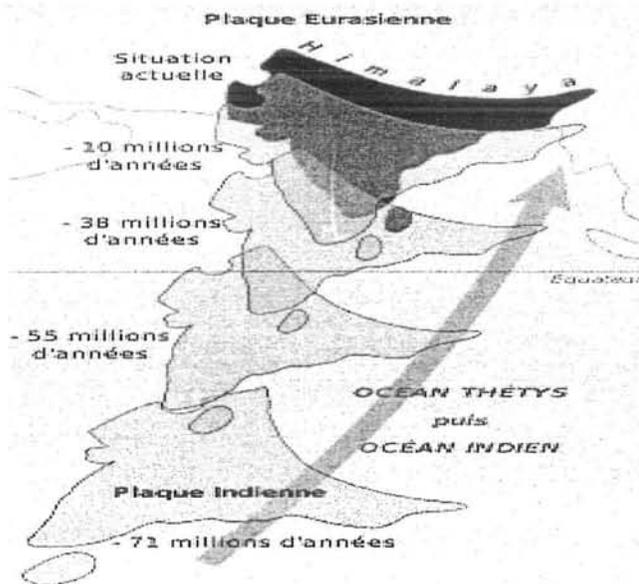

Fig.2.1: Regional tectonic map showing Northward Drift of Indian Plate (www.googlemaps.com)

2.4 TECTONOSTRATIGRAPHIC ZONES OF PAKISTAN

Tectonically speaking Pakistan consists of two broad geological divisions, the Gondwanaian Domain and Tethyan Domain (Kazmi and Jan 1997). Pakistan is divided into the following broad tectonic zones Indus platform and fore-deep

- East Balochistan fold-and-thrust belt
- Sulaiman–Kirthar Fold Belt
- Bela–Zhub Ophiolitic thrust belt
- NW Himalayan fold-and-thrust belt
- Indus Suture Zone (MMT)
- Kohistan–Laddakh magmatic arc
- Main Karakoram Thrust (MKT) / Shyok suture zone
- Karakoram block
- Kakarkhorasan flysch / molasses basin
- Makran Accretionary zone and Kharan basin
- Chagai–Ras Koh magmatic arc
- Pakistan offshore
-

Basin is an area characterized by regional subsidence and in which sediments are preserved for the longer periods of time. In a basin a receptacle or container, which is basin's substratum is called the Basement. The container fill or content, which is the accumulation of sediments resting on the basement, is called a

called the Basement. The container fill or content, which is the accumulation of sediments resting on the basement, is called a Sedimentary cover. The gradual settling of the basin is called Subsidence. The point of maximum sedimentary accumulation is called the Depocenter. The depocenter may not correspond to the zone of maximum subsidence.

Pakistan comprises the following three sedimentary basins (Ahmed ,1998):

- Indus Basin
- Balochistan Basin
- Pishin Basin/ Kakar Khorasan Basin (kadri, 1995).

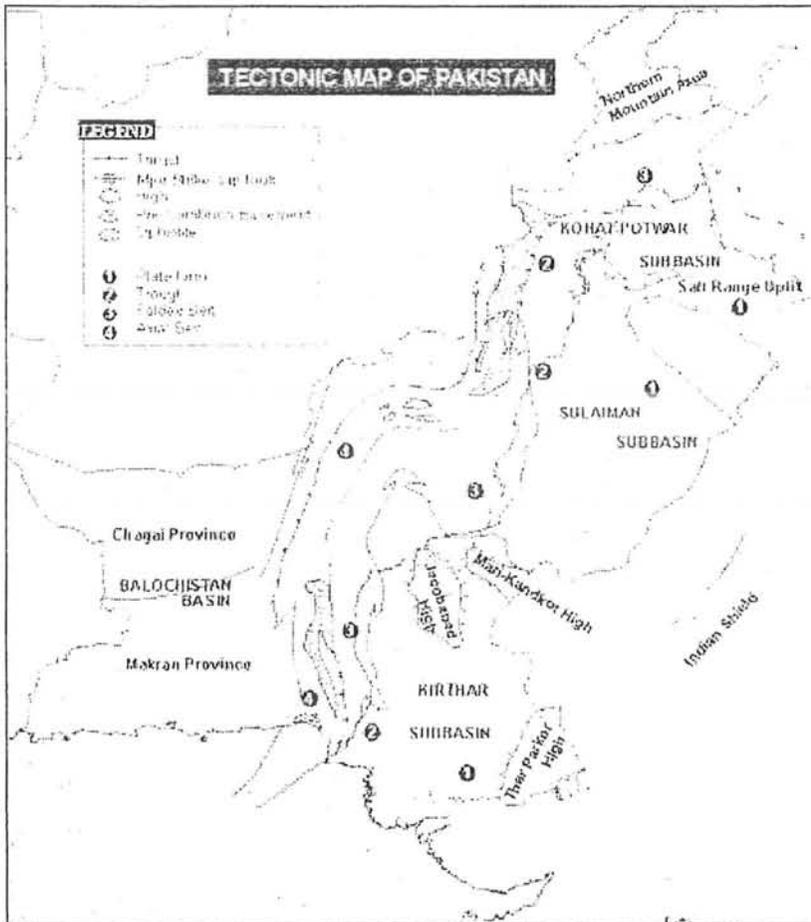

Fig.2.2: Tectonic map showing the main tectonic zones of Pakistan (Kazmi & Jan, 1997)

2.5 GEOLOGICAL EVOLUTION OF THE SOUTHERN INDUS BASIN

Better understanding of geological evolution of the basin may provide strategies for new oil and gas discoveries in Pakistan. A geological history of the basin can be compiled by considering the basin forming tectonics and depositional sequence. The western margin of Indo-Pak continental plate is characterized by past extensional tectonics resulting in rifted protocontinent and new oceanic crust during sea floor spreading. The new oceanic crust was formed at a rate matching the continental separation similar to divergent associated with fossil rift in Africa, Europe and north Atlantic.

Zaigham and Malik proposed a structural model for the evolution of southern Indus basin.

1. This corresponds to the initial rifting of the super continent Gondwanaland, probably during the Paleozoic. The divergent phenomena includes the formation of Basaltic magma in the upper part of the Asthenosphere, causing broad tectonic up warp and thinning of the overlying Lithosphere, probably resulting from plastic flow in the lower part and extensional faulting in the upper part. The thinning of Lithosphere continued and resulted in the collapse of the tectonic up warp over the magma blister and subsequently the process of sea floor spreading began with basaltic magma upwelling to the earth surface at oceanic Lithosphere.

2. Extensional forces broke the upper brittle crust into blocks separated by active faults during sea floor spreading. It appears that stretching of initial rifted part stopped at some geological time during very late Paleozoic to very early Mesozoic. The stretched crust remained as Indus basin failed rift in sediments started to accumulate.

3. The third step represents subsidence of the stretched continental crust and simultaneous accumulation of the Mesozoic and Tertiary sediments in the Indus basin.

Thick Cenozoic strata are exposed along the western margin of the Indus basin in the Kirther Fold and Thrust Belt. A few small isolated outcrops of Tertiary are exposed near Khairpur in the northern part and Hyderabad in the southern part.

Tertiary strata have also been reported from Jaisalmir and Ran Ketch areas. Unconsolidated quaternary sediments range between 30m and 200m thick in the southern Indus basin.

2.6 BASIN CLASSIFICATION OF THE SOUTHERN INDUS BASIN

This basin is located just south of Sukkur Rift, a divide between Central and Southern Indus basins. It comprises the following main units (Kadri, 1995).

- Thar Platform
- Karchi Trough
- Kirthar Foredeep
- Kirthar Fold Belt
- Offshore Indus

The platform and trough extend into the offshore Indus.

The Southern Indus Basin is bounded by the Indian Shield to the east and the marginal zone of Indian Plate to the west. Its southward extension is confined by offshore Murray Ridge- Owen fracture plate boundary. The oldest rocks encountered in the area are of Triassic age. Central and southern Indus basins were undivided until Khairpur - Jacobabad High became a prominent positive feature. This is indicated by homogeneous lithologies of Chilton Limestone (Jurassic) and Sember Formation (Lower Cretaceous) across the High. Sand facies of Goru Formation (Lower Middle Cretaceous) are also extending up to Kandhkot and Giandari area. This is further substantiated by Khairpur and Jhatpat wells located on the High. In Khairpur-2 well, significant amount of Lower Cretaceous and Paleocene is missing while in Jhat Pat-4, the whole Cretaceous and Paleocene are absent with Eocene directly overlying Chilton Limestone (Jurassic). Paleocene facies south of the High are quite different from that in north and are dominated by clastic sediments derived from the positive areas (Khairpur- Jacobabad High and Nabisar Arc).

THAR PLATFORM

It is a gently sloping monocline analogous to Punjab Platform controlled by basement topography. The sedimentary wedge thins towards the Indian Shield whose surface expressions are present in the form of Nagar Parkar High. It differs from the Punjab Platform in that it depicts the buried structures formed due to extension tectonism resulting from the latest counter clockwise movement of Indian Plate. It is bounded in the east by Indian Shield, merges into Kirthar and Karachi Trough in the west and is bounded in the north by Mari-Bugti Inner Folded Zone. The Platform marks very good development of Early/Middle Cretaceous Sands (Goru), which are the reservoirs for all the oil/gas fields in this region.

KARACHI TROUGH

It is an embayment opening up in to the Arabian Sea. The Trough is characterized by thick Early Cretaceous sediments and also marks the last stages of marine sedimentation. It contains a large number of narrow chain like anticlines, some of which contains gas fields (Sari, Hundi, Kothar). The Early Middle and Late Cretaceous rocks are well preserved in the area. It has been a trough throughout the geological history. The Upper Cretaceous is marked by westward progradation of a marine delta.

The most interesting feature of Karachi Trough is the reportedly continued deposition across the Cretaceous/Tertiary (K/T) boundary wherein Korara Shales were deposited, the basal part of which represents Danian sediments. This localized phenomenon probably represents a unique example where no hiatus in sedimentation occurred at the end of Cretaceous era. Elsewhere in Pakistan, a break in deposition marked by laterites, bauxites, coal etc. is a common feature across the K/T boundary.

KIRTHAR FOREDEEP

Kirthar Foredeep trends north south, which has received the sediments aggregating a thickness of over 15,000 meters. It has a faulted eastern boundary with Thar Platform. It is inferred that the sedimentation has been continuous in this depression. However from the correlation of Mari, Khairpur and Mazarani wells it appears that the Upper Cretaceous would be missing in the area. Paleocene seems to be very well developed in the depression but is missing from Khairpur – Jacobabad High area. This depression, like Suleiman Depression, is the area of great potential for the maturation of source rocks.

KIRTHAR FOLD BELT

This north-south trending tectonic feature is similar to Suleiman fold belt in structural style and stratigraphic equivalence. Rocks from Triassic to Recent were deposited in this region. The configuration of the Kirthar fold belt also marks the closing of Oligocene- Miocene seas.

The western part of the Kirthar fold belt adjoining the Balochistan basin, which marks the western edge of the Indus Basin, is severely disturbed. This western margin is associated with hydrothermal activities, which resulted in the formation of economic mineral deposits of Baryte, Fluorite, Lead, Zinc and Manganese.

OFFSHORE INDUS

This area forms the part of passive continental margin and appears to have gone through two distinct phases of geological history

(Cretaceous-Eocene and Oligocene- Recent). Sedimentation in offshore Indus region started from Cretaceous time. However deltaic and submarine fan sedimentation has occurred since middle Oligocene time with the inception of Proto-Indus System.

Offshore Indus is divided into Platform and depression along a Hinge Line in close proximity and parallel to 67° E Longitudes. Offshore Platform is divided into Karachi Trough and the Thar Platforms deltaic area by a line, which divides Karachi Trough from Thar Slope onshore (Kadri, 1995).

2.7 TECTONIC OF SINDH MONOCLINE

Tectonics of Indian platform of which Sindh monocline forms a part has been discussed by many authors. The northward movement of Indian platform generated compression where accompanying anticlockwise rotation produced tension. As a result of tension the platform was split into grabens and horst. This tectonic setting provided the ideal condition for widespread deposition of sediments exhibiting a variety of facies, including organic rich Sembar shale (Source rock) and highly porous and permeable Lower Goru sands. (Reservoir Rock) .

Two sets of faults indicating two different episodes of rifting are developed in the platform. The first set of faults associated with early cretaceous Kutch rift phase and the second set is a consequences of Late cretaceous Cambay rift phase.

A very investigation feature can be observed while looking at the map of these discoveries. The gas and condensate fields are concentrated in the north eastern and south western parts of monocline. Whereas the oilfields are restricted to the center of the area on the basis of the concentration of the gas, oil and condensate fields, the authors infer that late cretaceous Cambay rift divided Sindh monocline into Mithrao Tando Ghulam Ali Graben, Pakistan Bari Horst and Daru Nur Grabens.

2.8 HYDROCARBON POTENTIAL OF THE AREA

The study area lies in the extensional regime. Tectonically it is not so much complex but due to extensional regime normal faulting has been occurred in the area during the first stages. These normal faulting form horst and grabben and half grabben structures which are very important for hydrocarbon accumulation and are good structural trapes. The area has very rich source and reservoir rock formations.

SOURCE ROCKS

Source rock is the productive rocks for hydrocarbons. They also initiated the conversion of organic compound into oil and gas form. The Formations, which act as source rocks in the project area are as follows.

Sember Formation is believed to be the source of hydrocarbons in Badin platform field and huge gas accumulation in Sulaiman province. Potential reservoir occurs within the sand stone of formation. Ranikot shale was used to be considering as the main source for all the gas present in that region. The Upper Goru sand act as a good source rock in Sindh Monocline.

RESERVOIR ROCKS

The rocks that contain the hydrocarbons have the porosity as well as permeability is as follows Chilton Limestone, Lower Goru Formation, Parh Limestone, (No oil or gas shows have been found in Parh limestone).

CAP ROCKS

The rocks that act as a cap rock and used to seal the hydrocarbons are called Seal rocks. These should be impermeable. The following formations act as seal rock in the Study area are Ranikot formation, Goru Formation and Sember formation.

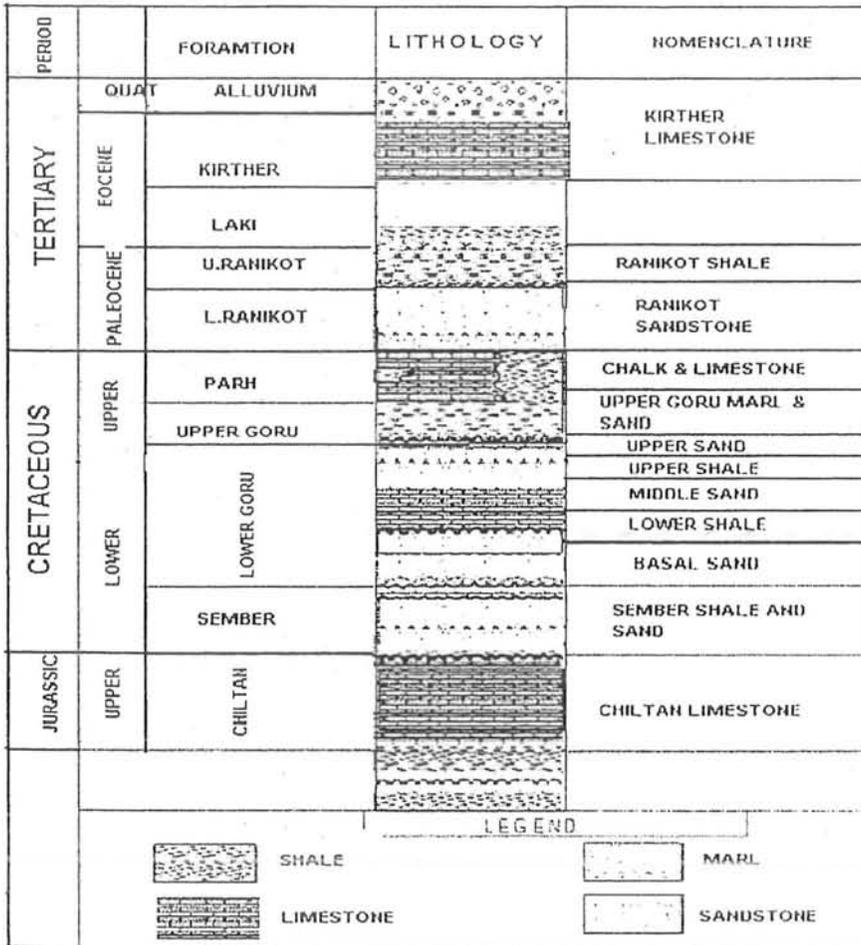

Fig.2.3: Stratigraphic Column of Southern Indus Basin showing the stratigraphic units from Jurassic to Tertiary.

2.9 FUTURE PROSPECTS

Aero magnetic data indicate a deep seated NS trending fossil failed rift in the Southern Indus Basin on the western margin of the Indo-Pakistan continental plate. Horst and Graben structures have been identified in the subsurface associated with Indus fossil rift. The deep and extensive sedimentary basin, known as the Southern Indus Basin, appears to have a developed owing to creation of the failed rift and subsequent subsidence and sedimentation processes. The distribution of the seismic epicenters in the Indus plane exhibit a close association with the regional EW trending system of transcurrent faults related to the Indus Basin fossil rift, which seems to be active even at present, causing deformation of the overlying mountain ranges and geomorphologic features. The presence of the fossil failed rift has identified encouraging prospects of new discoveries of oil and gas in the

Southern Indus Basin, because favorable conditions related to the sources, earth heat, reservoirs and seals prevail in the proposed geological models. The present basement interpretation, combined with the presence of known hydrocarbon source beds, reservoirs, and structures found in the surrounding basin should be further interpreted to delineate new exploration target as the vast tracts await drilling in the Southern Indus Basin.

DATA ACQUISITION

3.1 INTRODUCTION

The seismic methods utilize the fact that seismic waves travel with different velocities in different rocks. The principle is to initiate such velocities at a point and determine at a number of other point, the travel time of energy that is refracted or reflected by the boundaries between different rocks formations, when enable the position of the boundaries to deduced.

There of two types of methods in seismic prospecting

- Seismic Refraction method.
- Seismic Reflection method.

3.1.1 SEISMIC REFRACTION METHOD

Refraction method base on the study of elastic waves refracted along geological layer. This method is generally used for determining low velocity zone (Weathering layer). This method is used as supplement with refraction method.

3.1.2 SEISMIC REFLECTION METHOD

This method is based on the study of elastic waves, which are reflected from subsurface interface between two geological layers. These layer differ from each other in densities, velocities and product of density and velocity is called Acoustic impedance. When a seismic wave strikes the interface of two layers having acoustic impedance contrast, it is reflected back. The seismic reflection is very powerful tool being widely used in oil and gas exploration.

Depth of reflecting interfaces can be estimating from the recorded time and velocity information that can be obtain either from reflected signal themselves or from surveys in well.(Dobrin & Savit, 1988).

3.2 SEISMIC DATA ACQUISITION

The basic field activity in seismic surveying is the collections of seismogram which may be define as analog or digital time series that register the amplitude of ground motion as a function of time during the passage of seismic wave train.

The acquisition of seismogram involves conversation of the seismic ground motions into electrical signals, amplification and filtering of the signal and their registration on a chart recorder and / or take recorder. Kearey,et al.(1996)

According to (Robinson and Coruh,1988) the component which are involve in collection of seismograms, are:

- Input source

- Profile array
- Recording instruments

3.2.1 INPUT SOURCE

Input devices are used to produce vibrations in the ground; different kinds of input sources include impulsive as well as non impulsive sources.

IMPULSIVE ENERGY SOURCES

Sources include dynamite, ammonium nitrate, which are available in different sizes. For most seismic surveying the explosive charge is detonated in a hole. The depth of this shot hole can range from few feet to hundreds depending on various circumstances. Explosives can be used for marine surveying but other more convenient devices are satisfactory for many purposes, one such device capable of producing strong impulses of energy is called as Air gun.

NON IMPULSIVE SOURCES

Explosives are very effective for producing seismic waves, but the potential for destructive side effects and the time, cost and inconvenience of drilling shot holes provides incentive for developing alternate energy sources. Much seismic surveying must be done along public roads ways where permits for drilling and detonating explosives can be difficult or impossible to obtain. The best alternative is the vibroseis system.

In the vibroseis system a pad pressed firmly to the ground produces energy, which vibrates in a carefully controlled way. The pad, which is about one square meter, is attached beneath a truck by a hydraulic jack. Extending these jacks allows the weight of the truck to be used to press the pad to the ground. The vibration produce of varying frequencies called sweep signals. The vibrations that vary from low frequency to higher and from higher frequency to lower are called upsweep and down sweep respectively. The typical sweep signal last for seven or more seconds and varies in frequencies between limits of about 10 and 80 Hz.

3.2.2 SOURCE/RECEIVER ARRAY

The purpose of the shots and geophone arrays in cancellation of some noises e.g. ground roll enhancement of signal.

Real earth structures posses more irregular boundaries and some velocities difference from place to place in a layer. Seismic profiling helps us to resolve these variations more accurately.

Following are some spreads being used in seismic reflection methods.

BASIC SPREADS

In seismic reflection surveys the arrangement of the geophones that are used to record data is called spread. The interpretation of seismograms is simplest if the geophones are arranged in straight lines. The basic straight line spreads are given below:

END SPREAD

The shot point is located on the side of the spread in which geophones are arranged in straight line.

IN-LINE OFFSET SPREAD

It is a modified form of end spread in which shot point is located on one side, some distance away from the first geophone.

SPLIT SPREAD

Geophones are arranged on either side of central shot point.

CROSS SPREAD

The geophones are arranged in a cross shape around the central shot point.

L-SPREAD

Geophones are distributed around the shot points as an L-shape.

3.2.3 RECORDING INSTRUMENTS

GEOPHONE

The receiver used to detect ground vibrations is called a geophone or a seismometer. It is used for seismic surveying on land and it can be operated on the ocean floor if mounted in a suitable container. Most common type of geophone is moving coil geophone. It consists of a cylindrical coil that is suspended from a spring support in the field of a permanent magnet that is attached to the instrument casing. The magnet has a cylindrical pole piece inside the coil and an annular pole piece surrounding the coil.

Due to ground vibrations the coil starts to oscillate and its motion in the magnet field generates the voltage across the terminals of the coil. The geophone is fixed by a spike base into soft ground or mounted firmly on hard ground. Kearey, et al. (1996)

The geophone signals are transmitted to the recording system by means of seismic cables.

3.3 RECORDING SYSTEM

- Analog recording system
- Digital recording system

3.3.1 ANALOG RECORDING SYSTEM

Analog techniques are old techniques which produce continuous graphs. The graphs are obtained either on papers or magnetic tape that represents the variation in amplitude with respect to time, of seismic waves.

3.3.2 DIGITAL RECORDING SYSTEM

The technique of recording the geophone output at discrete moments is called digital recording because the recording consists of series of digits or numbers. Later these numbers can be plotted and the seismogram prepared by connecting the points. (Robinson & Coruh, 1988).

The digital data is recorded on a magnetic tape in the form of binary numbers. Each digit of binary number on the tape is called a byte. If the recording head magnetize this byte then it indicates "1" otherwise it is "0".

Digital recording system has following units:

MULTIPLEXER

It is a high speed electronic switch that first picks the signal of channel-1 for a period of one micro second and charges its capacitor. Then it takes the signal of channel -2, then to channel-3 and so forth up to last channel. Then again it switches channel-1 and repeats the same procedure. Hence the data recorded, will be in multiplex form.

AMPLIFIER

The recording signals are then amplified by passing through the amplifier and then these signals are transmitted to the A/D converter.

A/D CONVERTER

Here the amplified analog signals are converted into digital signals. In A/D converter different combinations of standard voltages are generated and tested to find the particular combination that exactly balances the signals. The voltages making up the combination are transmitted to the formatting unit.

FORMAT

In format generator in the voltage pulses are converted to control signals that activate the recorder head to magnetize the appropriate bits on the

magnetic tape. This entire sequence for channel-1 requires less than 30 microseconds.

3.4 SEISMIC NOISE

All type of disturbances created and interference with the signal of interest is called a noise. Noise is divided into two types.

- Coherent Noise.
- Incoherent Noise

3.4.1 COHERENT NOISE

Coherent noise displays some regular patterns on a seismogram. Often it consists of recognizable waves such as surface waves, refracted waves and multiples that are produced by the source.

3.4.2 INCOHERENT NOISE

The coherent noises are caused by natural factors like rain, wind blowing, moving of vehicles etc. Incoherent noise displays no systematic pattern on seismogram.

3.5 INTRODUCTION TO SEISMIC DATA PROCESSING

Data processing is an approach by which the raw data recorded in the field is enhanced to the extent that it can be used for the geological interpretation. (Sadi,1980).

3.6 AIM AND PURPOSE

The basic aim and purpose of data processing is to produce a perfect seismic section by applying a sequence of correction. Actually the seismic reflections from the depth are generally weak and need to be strengthened by digital processing of field data. (Robinson & Coruh,1988)

This approach involves the sequence of operation for improving signal to noise ratio.(Dobrin & Sovit, 1988).

The seismic field recorder generally records the data on magnetic tape. These tapes are then transferred to the data processing centre. Where the seismic data is processed. Processing seismic data consists of applying a sequence of computer program.

3.7 PRIMARY STAGES AND PROCESSING OF SEISMIC DATA

According to Yilmas 1987 there are three primary stages in Processing Seismic Data. In usual order of application they are:

- Deconvolution.
- Stacking.

- Migration

3.8 PROCESSING SEQUENCE

The seismic data processing sequence can be broadly defined in five categories. (Yilmaz, 2001)

- Data Reduction
- Geometric Corrections
- Data Analysis and Parameter Optimization
- Data Refinement
- Data Presentation

In Figure 3.1 a systematic diagram is given below explains the stages involved in data processing. (Rehman, 1989).

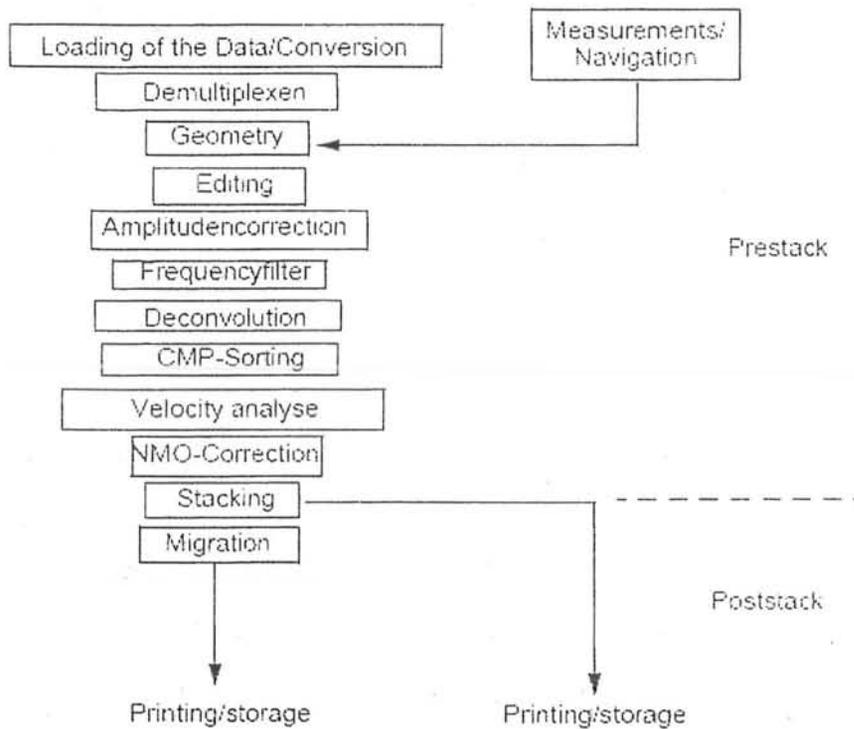

Fig 3.1:Diagrammatic block diagram showing the various stages of seismic processing modified from(Rehman,1989)

3.8.1 DATA REDUCTION

Data reduction is done by certain processing operations as discussed below.

- Demultiplexing
- Geometry definition
- Correlation

- Header generation
- Display
- Editing and muting
- Amplitude adjustment

DEMULPLEXING

Data from the field arrive at the processing center in tapes written in multiplexed format, because that is the way the sampling is usually done in the field, successive samples on the tape represents the succession of channels at the same instant of time. Most reflection seismic data are now being recorded on digital magnetic tape unlike analog seismogram which are recorded in form suitable for analysis, digital seismogram must be assembled from the digital tape by a sorting process. This sorting process is called Demultiplexing. Successive sample on the tape represent the succession of channels at some instant in time. Multiplexed data thus used time, not channels at the primary index.

In general the early stages of processing require channel ordered or trace ordered data. Channel Demultiplexing data in this form. First the computer reads the entire digital tape, then it repeatedly Stores a value count pass another "m", value and so until the following sequence have been compiled separately.

This unscrambling of multiplexed array into a trace sequent array is called Demultiplexing.

So Demultiplexing is accomplices by a simple compute sorting program and is the first in any Data processing sequence. (Rehman, 1989) .

| PROCESS | PURPOSE | WHEN APPLIED |
|----------------|--------------------------------------|--------------|
| Demultiplexing | Put data into trace sequential order | First |

GEOMETRY DEFINITION

The layout of receivers for each shot record the location of all shots along the line, and all such field information must be described in detail to the

computer for the geometry-specification step. Most geometry programs can access the digitized base-map file.

Computer access is particularly necessary for processing crooked lines in which sources and receivers are not uniformly distributed along a straight traverse. The geometry program must calculate a source-receiver mid-point based on the two ground locations. All relevant geometric information is retained in the trace headers on the tape so that each trace is uniquely and accurately located. Later programs will time shift or filter as a function of ground location, offset, and/or other spatial coordinate(s) and time.

CORRELATION

Correlation is simply the measurement of similarity or time alignment of two traces. Since correlation is a convolution without reversing the moving array, a similar frequency domain operation also applies to correlation. (Yilmaz, 2001).

There are two types of correlation;

- Cross Correlation
- Auto Correlation

CROSS CORRELATION

Cross correlation measures how much two time series resemble each other. It is not commutative; output depends upon which array is fixed and which array is moved. As a measure of similarity, cross correlation is widely used at various stages of data processing. (Yilmaz, 2001).

AUTO CORRELATION

Correlation of a time series with itself is known as auto correlation. It is a symmetric function. Therefore only one side of the auto correlation needs to be computed. (Yilmaz, 2001)

VIBROSEIS CORRELATION

The signal generated by a vibroseis is not a short pulse but rather a sweep lasting some seven to ten seconds. The sweep is transmitted through earth and reflected signal. Each reflection is a near duplicate of a sweep itself, so the reflections in vibroseis record overlap and are indistinguishable. To make it useable reflections are compressed into wavelets through cross-correlation of data with original input sweep. After correlation each reflection on record looks similar to impulsive source data. This involves cross correlation of a sweep signal (input) with the recorded vibroseis trace. The sweep is a frequency-modulated vibroseis source signal input to the ground (Yilmaz, 2001). There are two types of sweep;

- Up Sweep (When frequency of the vibroseis source signal increases with time)
- Down Sweep (When frequency of the vibroseis source signal decreases with time)

IMPORTANCE OF VIBROSEIS CORRELATION

For vibroseis source, we have a sweep (a train of waves) rather than a short pulse/source wavelet whereas most seismic impulsive sources generate a very short pulse which can be used directly to examine subsurface structure. Vibroseis sweep lasts for several seconds depending upon the sweep time. So in case of vibroseis source all reflected and refracted signals on a vibroseis seismogram overlap one another extensively. Even after demultiplexing of the vibroseis seismogram it is impossible to recognize the reflections. So vibroseis correlation procedure is applied (Robinson. & Coruh, 1988).

Vibroseis correlation enables us to extract from each of the long overlapping sweep signals on vibroseis seismogram, a short wavelet much like those obtained with seismic impulsive source

HEADER GENERATION

Trace header information may include location and elevation of source and receiver, field record number, trace number etc. A real header block is also placed at the head of each reel, for recording line number, reel number etc.

DISPLAY

At any point of processing sequence the seismic analyst can display the data in wiggle trace or other modes. The choice of display is a matter of the client taste, but is not affected by company dictum. Currently, the data provided by OGDCL is the variable area with wiggles plot.

EDITING AND MUTING

Raw seismic data contains unwanted noise and sometime dead traces due to instrumental reasons. Thus the quality of data recorded is first observed by visual examination of raw field traces. Data may be affected by following reasons

- Polarity reversals in data
- Poor traces as well as poor bits

To remove polarity reversal, trace with reverse polarity is multiplied with it that becomes a trace with the polarity. Therefore editing is a process of removing or correcting traces, which in their original recorded taken, may cause stack deterioration. (Rehman, 1989). After doing this all the contributing traces

per each CDP are gathered together. Each trace in one CDP is identified by its shot point and receiver numbers. The CDP-gathers may be displayed as such for direct inspection and checking of edited data

Trace-muting is a special type of data editing. This term is applied for process of zeroing the undesired part of a trace. In order to avoid stacking non-reflection events (such as first arrivals and refraction arrivals) with reflection, the first part of the trace is normally muted before carrying out the stacking process. This is occasionally referred to as first break suppression (Sadi, 1980).

AMPLITUDE ADJUSTMENTS

Amplitude adjustment is done to recover the true information present in the data. True information means data is irrespective of effect produced due to wave propagation through the subsurface. It is well known fact that a seismic wave is attenuated as it travels in a non-perfectly elastic medium. Along with this effect, signal is further modified by recording station. So reflection amplitude recorded in the field is the end-result of the interaction of the following main factors

- Spherical divergence
- Inelastic attenuation

AUTOMATIC GAIN CONTROL

A gain recovery function is applied on the data to correct for the amplitude effects of wave front (spherical) divergence. (Yilmaz, 2001). This amounts to applying a geometric spreading function, which depend upon travel time, and an average primary velocity function, which is associated with primary reflections in a particular survey area. Gain is applied to seismic data for spherical spreading correction.

Often AGC (automatic gain control) is applied to raise the level of the weak signals. AGC attempts to make amplitudes similar for all off sets, for all time and for all mid points. (Dobrin & Savit, 1988). A typical method of calculating the median or average amplitude with in sliding windows down the trace, then to calculate the multiples needed to equalize the median value in all the window.

3.8.2 GEOMETRIC CORRECTIONS

In order to compensate for the geometric effects, we have to apply certain corrections on the recorded data. These corrections are called as geometric corrections (Dobrin & Savit, 1988). These corrections are applied on the traces gathered during trace editing and muting. The geometric corrections are

- Static correction
- Dynamic Correction

STATIC CORRECTION

Reflections are recorded at the earth's surface, which may vary in elevation, after they have passed through the weathered layer. The weathered layer may vary in both thickness and velocity.

1. Removing near surface effects is desirable so that:

Changes in reflection time across a stacked record section can be attributed wholly to subsurface effects.

Individual traces in CDP gather are properly aligned to preserve reflected signals when they are stacked.

2. Removing near surface effects requires two corrections

- Weathering Correction
- Elevation Correction

WEATHERING CORRECTION

A weathering correction replaces the actual travel time through the weathered layer by a computed travel time. The computed travel time would result if the weathered layer (the low velocity layer) were replaced by an equal thickness of the underlying higher velocity rock. Although the weathered layer does vary in thickness, its approximate thickness is usually known from previous experiences in the prospect area.

ELEVATION CORRECTION

The effects of topography on a trace's reflection times are removed by applying this correction, which, in effect, move both source and receiver vertically to a reselected datum surface. This surface is usually (but not always) a flat datum plane. (Rehman, 1989).

| PROCESS | PURPOSE | WHEN APPLIED |
|-------------------|--------------------------|--|
| Static Correction | Vertical time correction | Correct to at least a floating datum before NMO. May correct to final after stack. |

DYNAMIC CORRECTION

One of the steps of processing the data is to rearrange the traces to make CDP gathers. The trace from different records which correspond to the same depth points location, are collected together into a single record. The traces are normally arranged within this gather record in order of increasing

offset distance. Then the reflected signals from a single horizontal interface align along a hyperbola. The term normal move out or NMO means the variation in reflection travel time with off set distance from source to receiver. As shown in Fig 3.2

| PROCESS | PURPOSE | WHEN APPLIED |
|---------|-----------------------|----------------------|
| Dynamic | Horizontal Correction | Time Before stacking |

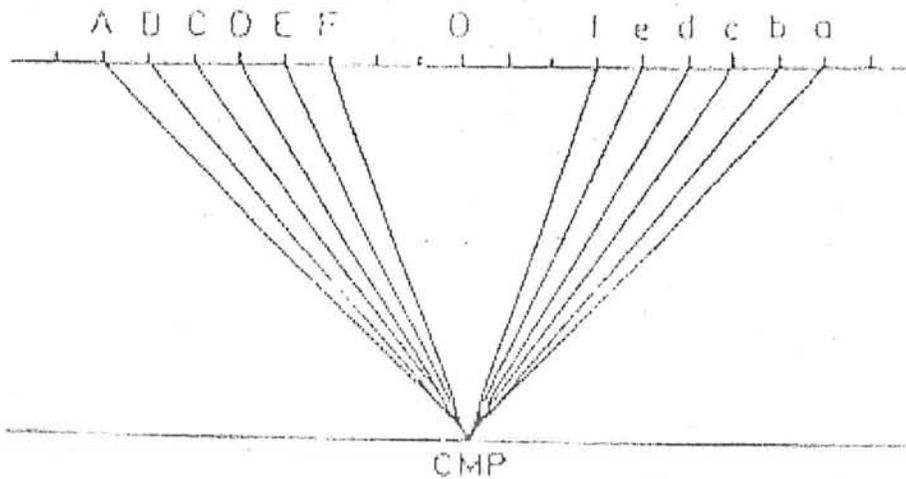

Fig 3.2 Shows Common Mid Point Gathers

3.8.3 DATA REFINEMENT

The processes described till now are used to make data free of the factors that decreases its quality. Also these processes are used to reformat the data and to diagnose its characteristics (Rehman, 1989). Data refinement consists of the following two main stages.

- Stacking
- Migration

Along with these two processes, there is another procedure occasionally used in data refinement and is called as Residual Statics.

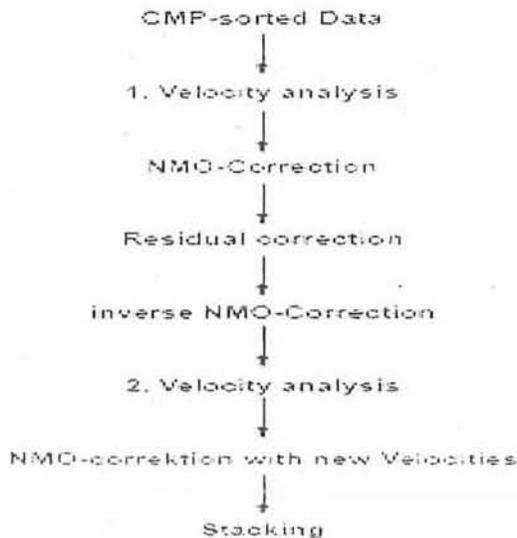

STACKING

Stacking is simply the process of adding up together the traces present in certain gathers, obtained during the seismic data acquisition. It is applied only when the all necessary corrections have been applied. The result of stacking is the corrected gather. In the "corrected gather" the traces have been gathered into the depth order. Both the static and dynamics corrections have

been applied to it and the traces have been muted (Dobrin & Savit, 1988). All that remains is to stack the data. Stacking result in a single stacked trace as an output for each depth point present in gathers.

One or other of two considerations is the basis for selecting the seismogram traces that will be stacked. Common offset stacking is done with traces that have the same source-receiver offsets, all of which are centered on the same point (Dobrin & Savit, 1988).

Scheme of residual static corrections

Stacking is a data compression of one to two orders of magnitude. The signal-to-random noise ratio is increased through an N fold stack by N. After stacking, the data are displayed at the surface location of the midpoint between source and receiver. When all adjustments to the data have transformed the offset data into time and phase coincidence with the zero offset traces, the common midpoint CMP and CDP are both widely often interchangeably. With dipping reflectors, the CMP after conventional processing is not the CDP. The correct positioning of reflection point will be by migration (Dobrin & Savit, 1988).

MIGRATION

The process of shifting the reflection points to the positions that correctly image the reflector and remove diffraction images, so that we may get an accurate picture of underground layers. If the reflector is flat, the reflection point will be located directly beneath the shot/receiver station, and the record section displays the event in its true position, plotted in time rather than depth (Robinson & Coruh, 1988).

However, if the reflector is not flat, the reflection point will not lie directly beneath the shot/receiver position, and the true position of the reflector

will differ from its apparent position. (Yilmaz, 2001). Figure 3.3 shows the subsurface dipping reflector's response.

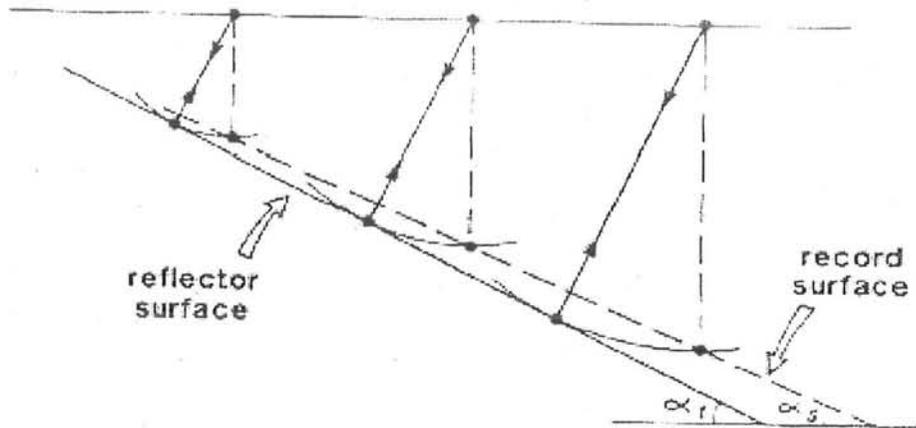

Fig:3.3 Seismic response form a dipping reflector, the recorded surface gives the apparent dip of the reflector surface (Rehman, 1989)

Therefore, migration is a tool used in seismic processing to get an accurate picture of the subsurface layer. It involves geometric repositioning of recorded signals to show a boundary or other structure, where it is being hit by the seismic wave rather than where it is picked up. Now, not only the position but the dip angle can be incorrectly imaged by vertically plotting. (Rehman, 1989).

IMPORTANT FEATURES OF MIGRATION

Following are the important features of migration (Rehman, 1989);

- Migration steepens the reflectors, as the dip angle of the reflector in the geologic section is greater than in the time section.
- Migration shortens the reflectors, as the length of the reflector on the geologic section is shorter than in the time section; thus, migration moves reflectors in the up dip direction
- When migration is applied in case of the undulating, reflector the crests become narrower and troughs become broad.

TYPES OF MIGRATION

With respect to the stage when migration is applied on the seismic data during processing, there are two important types of migration (Rehman, 1989).

- Pre-Stack Migration
- Post-Stack Migration

4.1. INTRODUCTION

In seismic, interpretation is defined as:

"The translation of seismic information into geologic terms" This process call for the greatest possible coordination between geology and geophysics, if it is carried out successful (Dobrin,1976)

According to (Dobrin and Savit,1988) interpretation is the transformation of the seismic reflection data into a structural picture by the application of correction, migration and time depth conversion.

4.2. MEANING OF INTERPRETATION:

The word interpretation has been given many different meanings to geophysicist who handle seismic reflection records and by geologists who put the information from them to use.

- Planning and programming
- Choice of field parameters
- Selection of processing procedure

After seismic map is constructed, an important part of it its interpretation is integrating the seismic data on it with geologic information from surface and subsurface sources e.g. fault traces or geologic contacts. This involves identifying reflectors and making tie to wells or surface features. All this depends upon the amount of information available.

Under favorable circumstances, interval velocities can be determined from reflection records with enough precision to permit them to serve as a basis for identifying lithology.

Geophysicist deals with the seismic section. In seismic method physical measurements are made at the surface, which are then interpretation in terms of what might be in the subsurface the position and behavior of interfaces, which gives rise to each reflection event is then calculated from arrival times. Resulting information is then combined into cross section, which represent the structure of geological interface responsible for the reflection event.

The seismic reflection interpretation usually consists of calculating the position of, an identifying geologically, concealed interfaces or sharp transition zones form seismic pulses return to the ground surface by reflection. The influence of varying geological condition is eliminated along the profiles to transform the irregular recorded travel times into acceptable subsurface models. This is very important for confident estimation of the depth and geometry of the bedrock or target horizons.

According to (Badely,1985). reflection seismic uses sound waves to investigate the subsurface. The acoustic impedance governs reflections, which is one of the rock properties.

Acoustic impedance = interval velocity *density

Reflections arise at boundaries across which acoustic impedance changes. No reflection occurs impedance does not change even if lithology changes. The greater the difference in the acoustic impedance is, the stronger the reflection. The size of change is defined by reflection coefficient (RC).

The major aim of seismic reflection surveying is to reveal as clearly as possible the structure of the subsurface. The geological meaning of seismic reflection is simply an indication of an acoustic impedance boundary where we want to know that whether this boundary marks a fault or a stratigraphic contact with any other boundary. We want to distinguish the feature that is not marked by the sharp boundaries.

A sequence of sedimentary rocks is grouped into unit called formations. These formations can be described in terms of age, thickness and lithology of the consistent layers.

To distinguish different formation by means of seismic reflection is an important question in interpretation of data, which may be structural, lithology, or stratigraphic.

4.3. APPROACHES TO THE INTERPRETATION OF SEISMIC SECTION

There are two main approaches for the interpretation of seismic section

- Structural analysis
- Stratigraphic analysis

4.3.1 STRUCTURAL ANALYSIS

This type of analysis is very suitable in case of Pakistan, as most of the hydrocarbons are being extracted from the structural traps. It is study of reflector geometry on the basis of reflection time. The main application of the structural analysis of seismic section is in the search for structural traps containing hydrocarbons. Most structural interpretation used two way reflection times rather depth and time structural maps are constructed to display the geometry of selected reflections events. Some seismic sections contain images that can be interpreted without difficulty. Discontinue reflections clearly indicate faults and undulating reflections reveal folded beds.

4.3.2 STRATIGRAPHIC ANALYSIS

This type of analysis is helpful in determining the very huge reservoirs of hydrocarbons. These area very rarely used, as it is work of sequence Stratigraphy which is somewhat complicated as compared to the structural analysis. Stratigraphic analysis involves the subdivision of seismic sections into sequence of reflections that are interpreted as a seismic expression of genetically related sedimentary sequences. The principles behind this seismic sequence analysis are of two types.

Firstly, reflections are taken define chrono stratigraphical units, since the type of rock interface that produce reflections are strata surfaces and

unconformities, by contrast the boundary of diachronous lithological units tend to be transitional and not to produce reflections.

Secondly, genetically related sedimentary sequences normally comprise the set of concordant strata that exhibit discordance with underlying and overlying strata. According to Dobrin and Savit, throughout the history of the reflection method, its performance in locating hydrocarbons in stratigraphic traps has been much less favorable than in finding structurally entrapped oil and gas.

Stratigraphic oil traps can result from reefs, pinchouts, or other features associated with erosional truncation, facies, and transition and sand lenses associated with buried channels, lakes, or similar sources.

4.4 SOLVING THE VELOCITY TIME PAIRS

On the seismic section we are given the V_{rms} . This RMS-Velocity is then converted into interval velocity (V_{int}). This interval velocity is then converted into average velocity (V_{avg}): After temporal interpolation of this average velocity at 10 ms, it becomes V_{avg} . (Interpolated) in the [VEL] format this is then used for time to depth conversion. This entire job is done using Velocity Analysis Software (VAS).

4.4.1 RMS VELOCITY GRAPH

The Root Mean Square Velocity functions given on a seismic section were processed by K-tron VAS (Velocity Analysis System) to compute interval & average velocity functions using Dix equation (1955).

$$V_{rms} = (\sum V_{int}^2 (T_i - T_{i-1}) / T_i)^{1/2}$$

The input velocity functions are Root Mean Square (RMS) Velocities, from these RMS velocities, we compute using VAS Interval and Average Velocities. The variation of R.M.S velocity with time can be seen in Fig 4.1 for line 856-SGR-58 and in Fig 4.2 for line 846-SGR-50. This graph shows the lateral and vertical behavior of R.M.S velocity information provided on the seismic section.

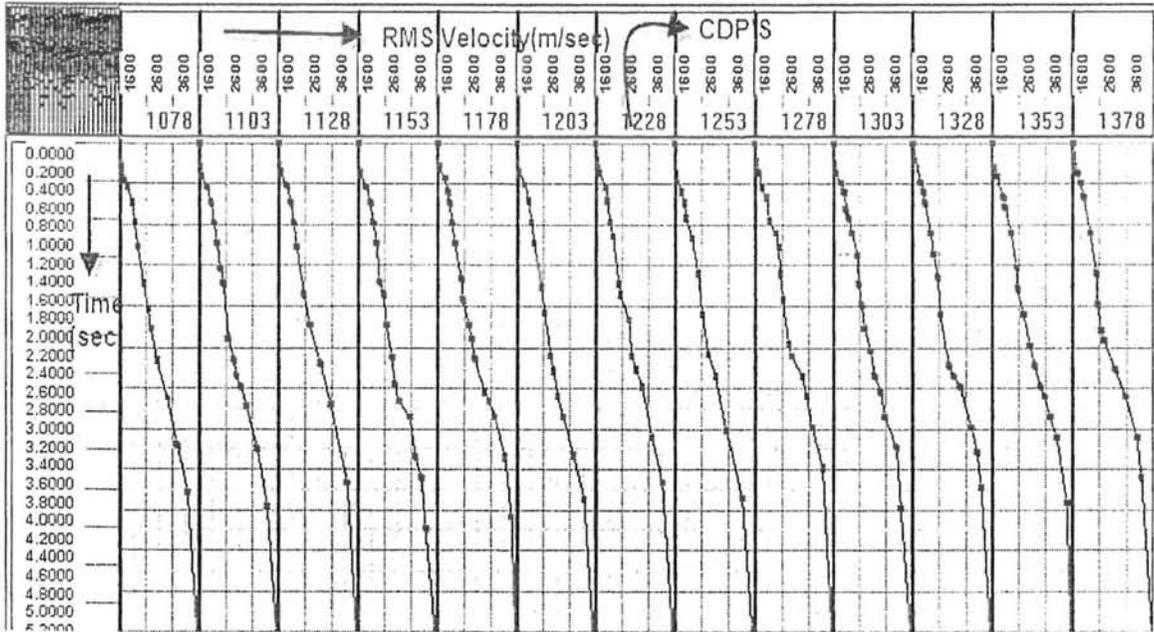

Fig 4.1 RMS Velocity Graph of Line 856-SGR-58

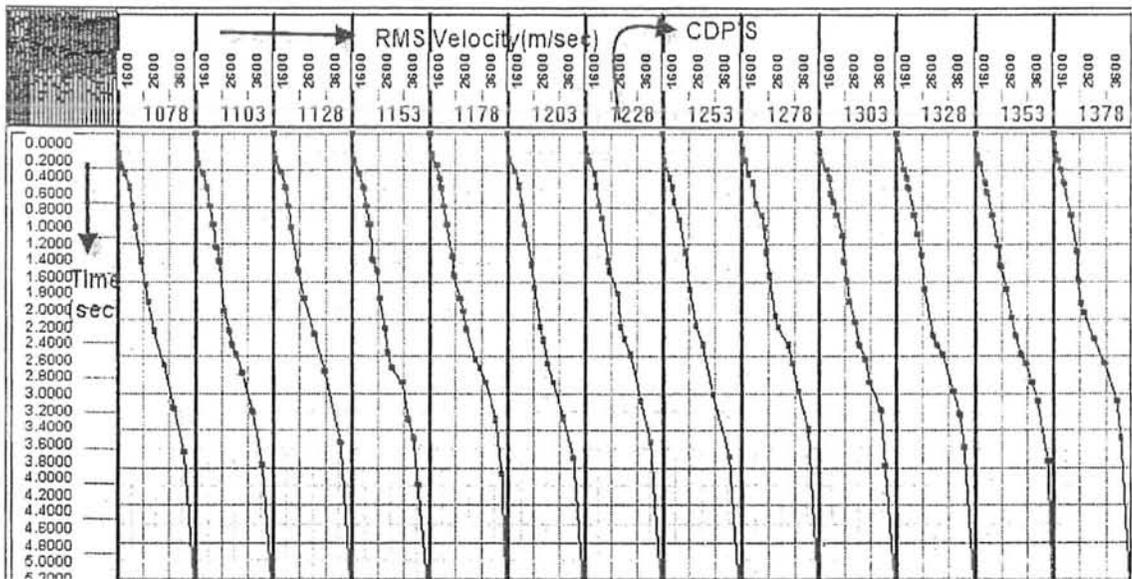

Fig 4.2 RMS Velocity Graph of Line 846-SGR-50

4.4.2 AVERAGE VELOCITY AND AVERAGE VELOCITY GRAPH

This is simply the depth 'z' of a reflecting surface below a datum divided by the observed one way reflection one way time 't' from the datum to the surface, so that

$$V_{AVE} = z / t$$

If 'z' represents the sum of the thicknesses of the layers $z_1, z_2, z_3, \dots, z_N$, then average

velocity defined as

$$V_{AVE} = (Z_1+Z_2+Z_3+\dots+Z_n) / (t_1+t_2+t_3+\dots+t_n)$$

Average velocity can be calculated by using the interval velocities provided on the seismic section using the Dix formula which is

$$V_{n,AVE} = (V_{n,INT}(t_n - t_{n-1}) + V_{n-1,AVE} * t_{n-1}) / t_n$$

From this, average velocities at constant interval of time can also be calculated and then use it for the "Average Velocity Graph". The purpose of preparation of this graph is to observe the vertical variation of average velocity from top to bottom.

The variation of Average velocity with time can be seen in Fig 4.3 for line 856-SGR-58 and in Fig 4.4 for line 846-SGR-50.

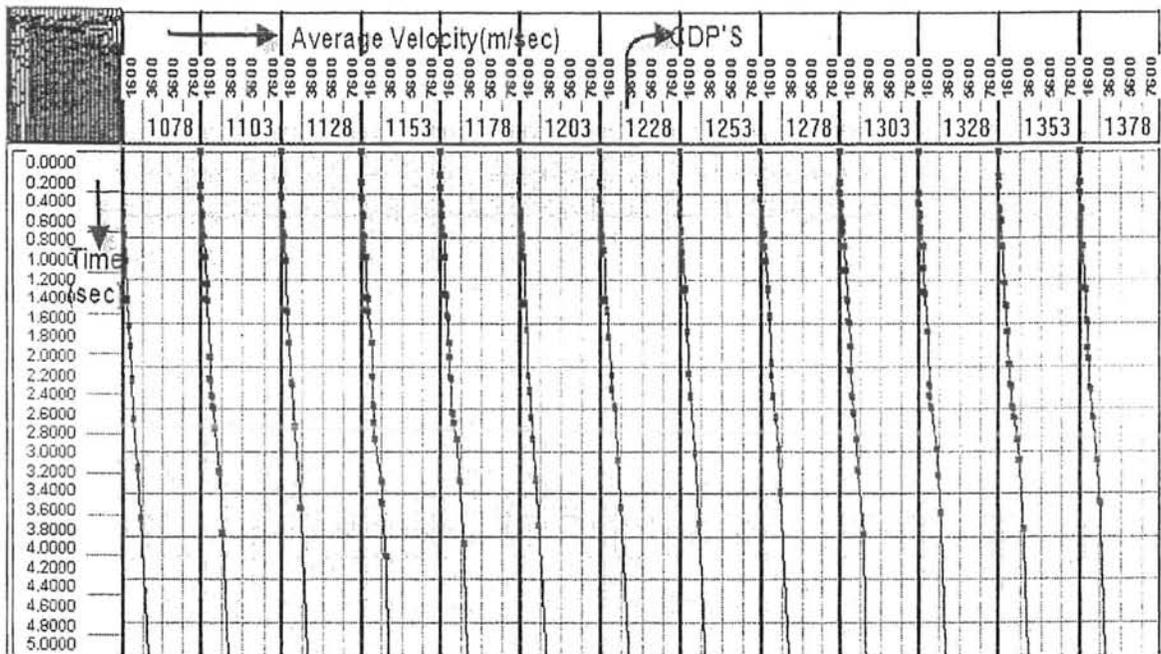

Fig:4.3 Average Velocity Graph of Line 856-SGR-58 This graph shows the lateral and vertical behavior of Average velocity

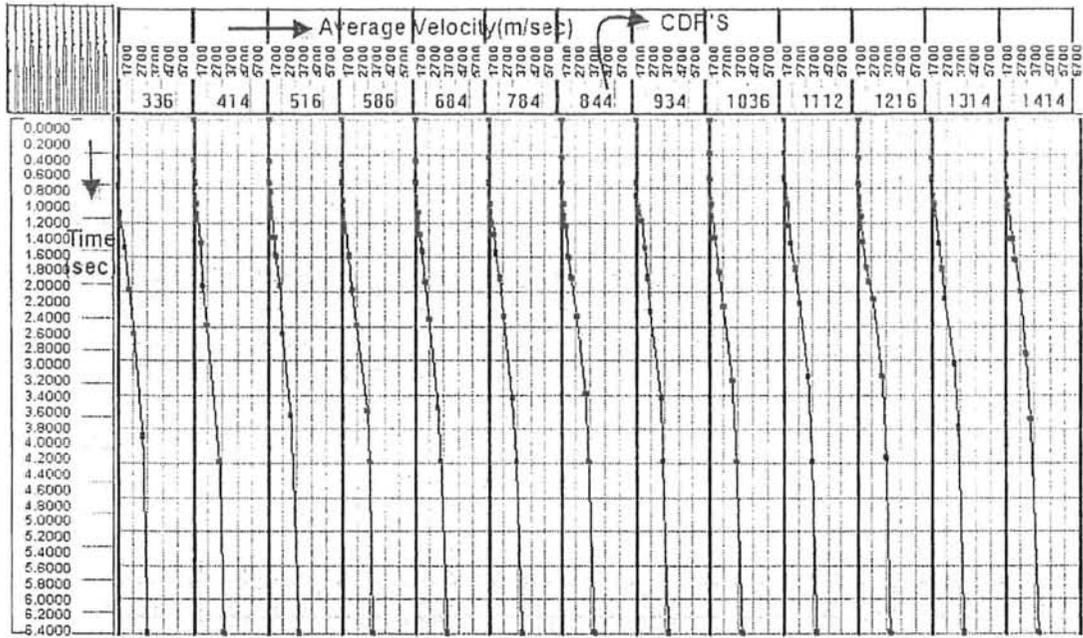

Fig:4.4 Average Velocity Graph of Line 846-SGR-50

4.4.3 INTERVAL VELOCITY

Interval velocity is the average velocity over some interval of travel path of the wave. It can be calculated by Dix equation, that is,

$$V_{n,int} = \frac{V_{n,rms}^2 \cdot T_n - V_{n-1,rms}^2 \cdot T_{n-1}}{T_n - T_{n-1}}$$

Where V_{int} = interval velocity in m/s, V_{rms} = root mean square velocity in m/s and T is the two way travel time of the seismic wave in millisecond.

Interval velocity is important because it may be used to determine the lithology.. These velocities are also used to determine the reflection coefficient of any particular reflector.. Average Velocity Graph is shown in Fig 4.5 for line 856-SGR-58 and in Fig 4.6 for line 846-SGR-50. For both lines interval velocity is decreasing after certain depth, this decrease may be due presence of hydrocarbon.

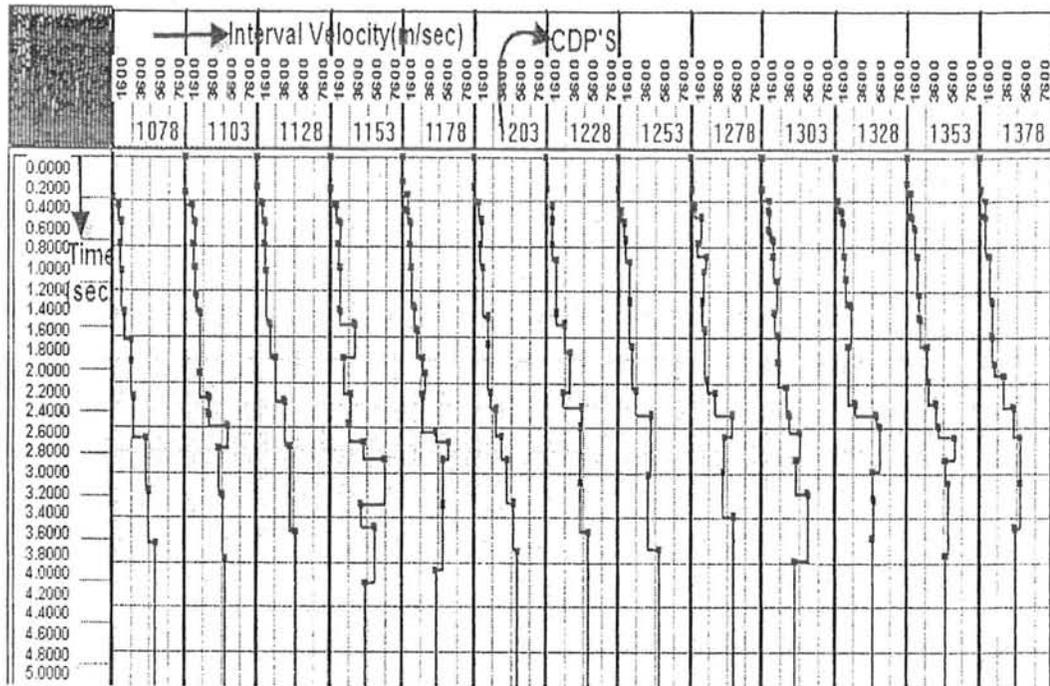

Fig.4.5. Interval Velocity graph of line 856-SGR-58 This Graph decrease in Interval Velocity at certain depth

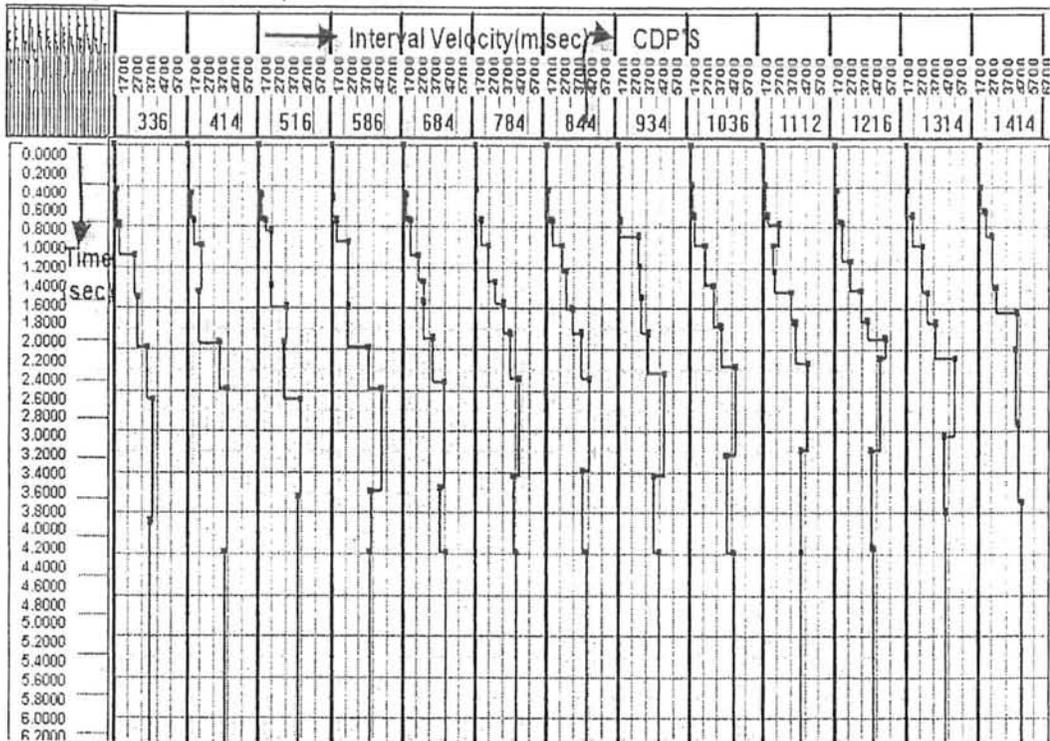

Fig:4.6 Interval Velocity graph of line 846-SGR-50.This Graph shows decrease in Interval Velocity at certain depth.

4.4.4 MEAN AVERAGE VELOCITY AND MEAN AVERAGE VELOCITY GRAPH

This is simply calculated by dividing the sum of average velocities at constant intervals of time with the total number of observations so that

$$V_{MEAN} = (V_{AVE 1} + V_{AVE 2} + V_{AVE 3} + \dots + V_{AVE n}) / n$$

Mean Average Velocity Graph is shown in Fig 4.7 for line 856-SGR-58 and in Fig 4.8 for line 846-SGR-50.

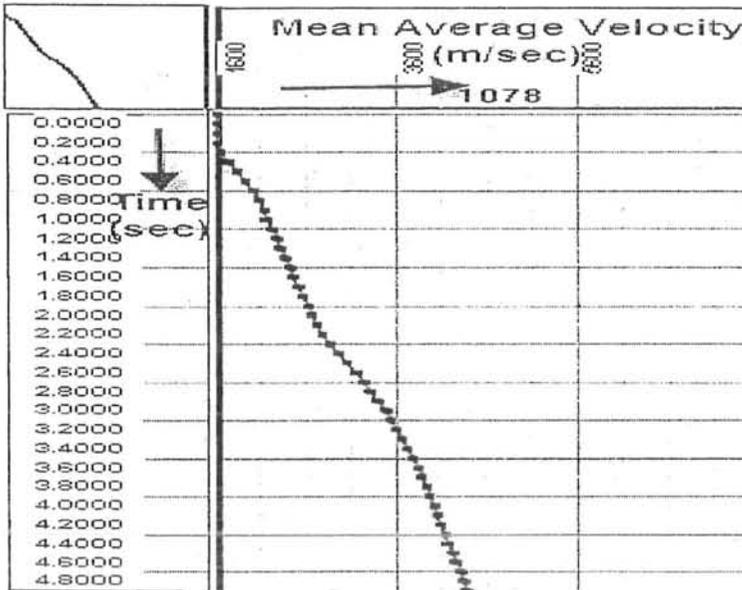

Fig:4.7 Average Velocity Graph of Line 856-SGR-56

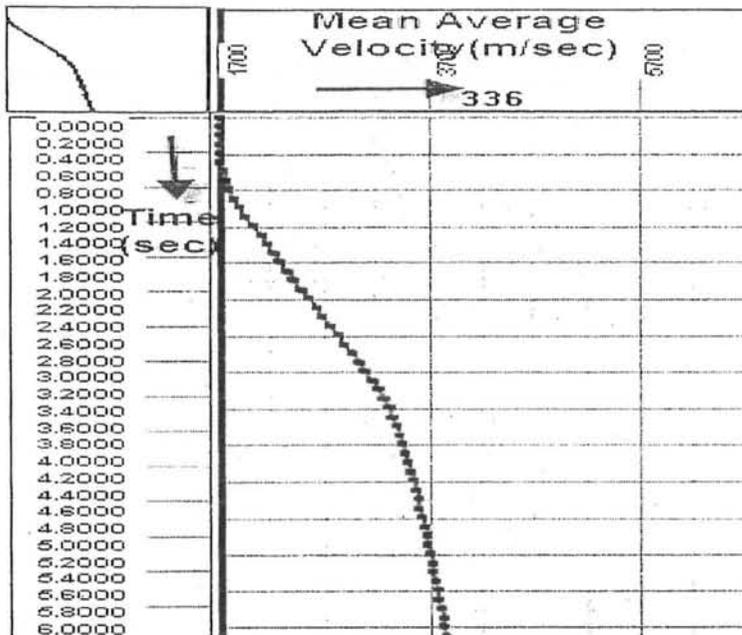

Fig:4.8 Average Velocity Graph of Line 846-SGR-50

4.4.5 ISO VELOCITY CONTOUR MAP

Whenever the CDP's are plotted against times at same average velocities, a section formed which shows the vertical variations of the velocity at different CDP's. The map so formed is termed as the Iso velocity map. It shows same velocity layers. If we consider that each stratigraphic layer has constant velocity through out the whole area and there is no lateral velocity variation, then Iso velocity map will be a very good representation of the seismic section. However this is an ideal situation, which is not the case here.

To generate ISO-Velocity Map K-Tron VAS generated a velocity grid by applying a temporal interpolation at 200msec and spatial 10 CDP'S interval. The final velocity data is transferred to Golden Surfer format translation programs written in OIL/Visual OIL K-Tron, et al. (2010) to generate iso velocity map. ISO-Velocity Map of line 856-SGR-58 is shown in Fig:4.9 ISO-Velocity Graph shows push up and push down, due to lateral variation in compactness.

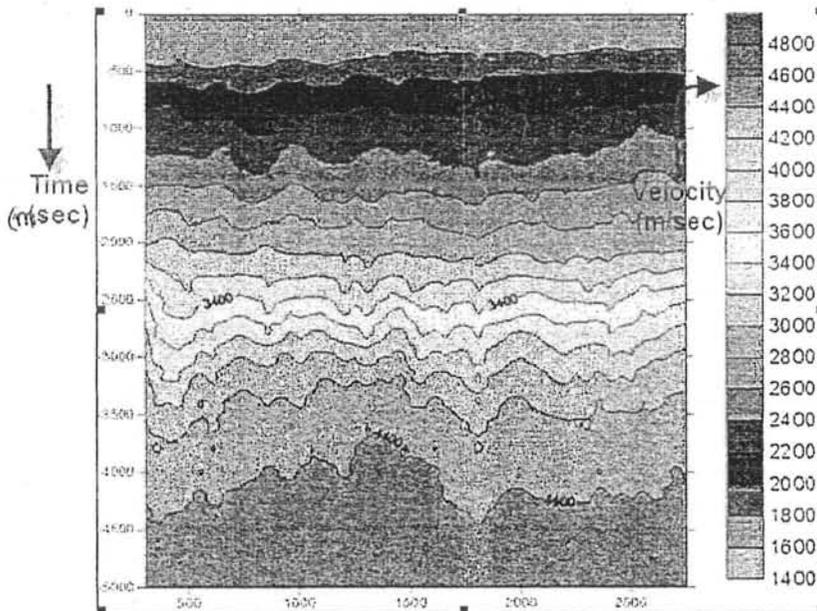

Fig:4.9 ISO-Velocity Map of Line 856-SGR-58.

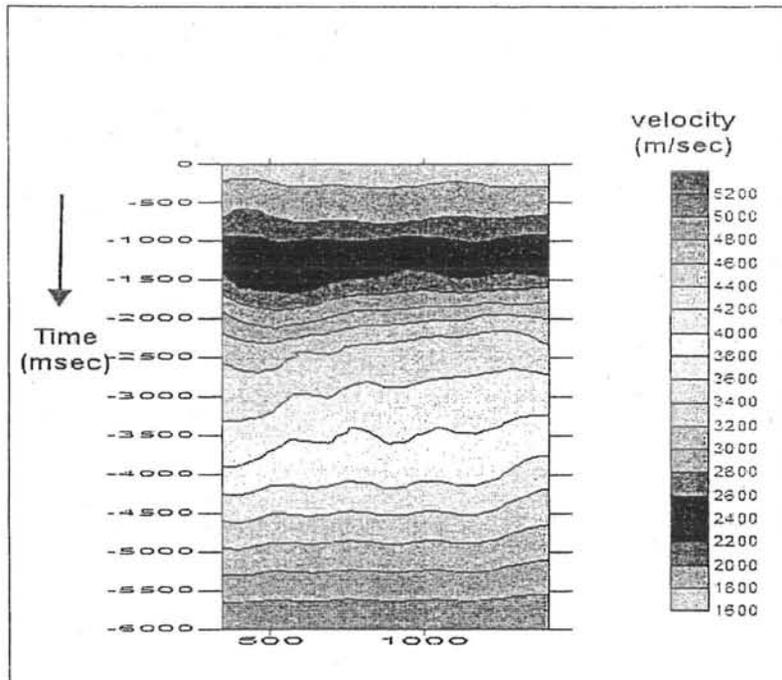

Fig:4.10 ISO-Velocity Map of Line 846-SGR-50

4.5.1 SEISMIC TIME SECTION

A seismic is picture or diagram of a cross section of the earth, composed of data from different seismic shots. In its usual form, it is made up of many wiggly line, or trace, show a modified version of the vibration of the ground at a specific point.

The wiggles on the trace start at a point near the top of the ground and go on down the paper, representing the points farther down into the subsurface. A section is made up of many traces, representing the vibration of the earth at a line of points on the ground.

A wiggle on a trace is an indication of difference between two kinds of underground rocks. The rocks in the sedimentary basin, like southern Indus basin, are usually in the form of layers of wide extent. So wiggle on one trace is usually accompanied by a similar wiggle on the next trace and so on, from the same lager of rock. A continuous line of the side by side wiggles is a seismic horizon. All the other necessary information is also given in the header of the seismic section.

To pick a reflection the most evident indication of the reflection is the dark band of the filled in peaks. To color a reflector, it is easy to decide to pick a peak and then color the trough area of a particular horizon. The color more reflectors it is better to choose the best reflection first, Deccan Trap in case of Sanghar others with the help of this one. Some times a horizon is difficult to pick, an interpretation of this one solely by the use of other

reflections is called as Phantom Horizon. The sambar formation of the Sarghar is the Phantom horizon.

For both lines four reflector are marked on Seismic Section. Seismic Time Section shows many Horst and Graben structures which may be favourable for Hydrocarbon accumulation.

The seismic time section for the line 856-SGR-58 is shown in fig 4.11 and for 846-SGR-50 is shown in Fig: 4.12

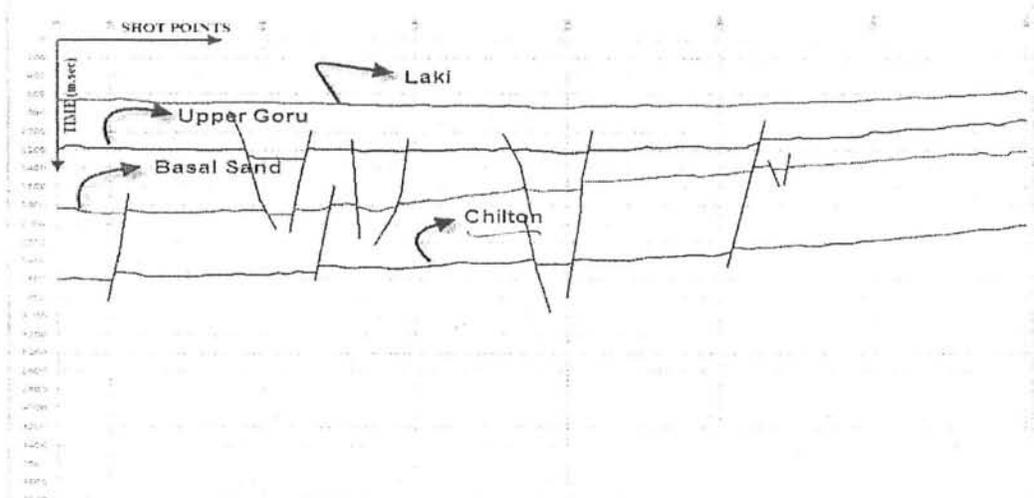

Fig:4.11 Seismic Time Section for line 856-SGR-58

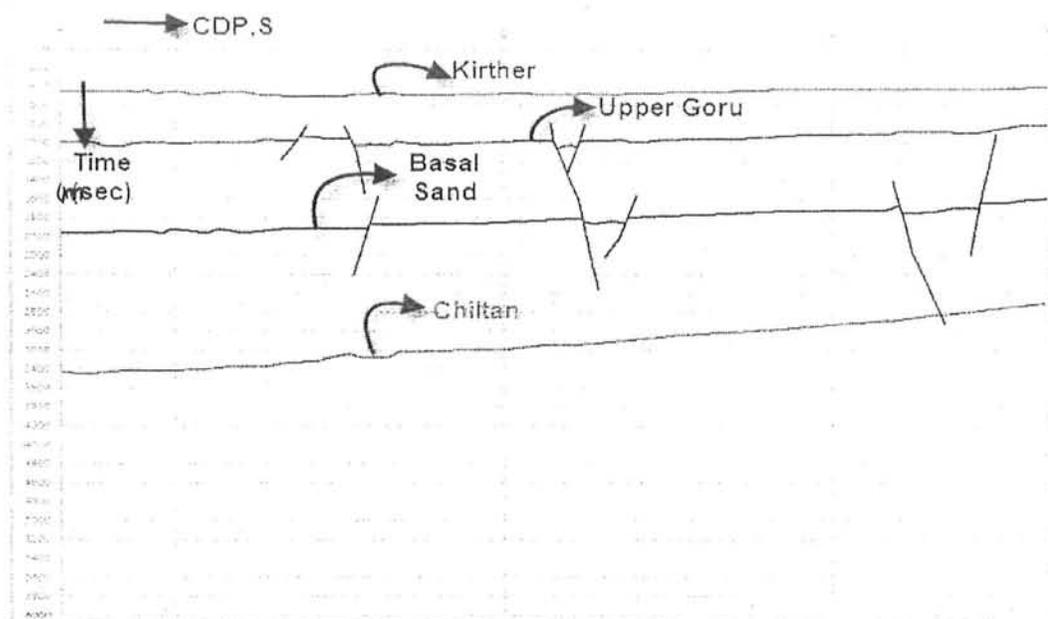

Fig:4.12 Seismic Time Section for line 846-SGR-50

4.5.2 DEPTH SECTION

When we make a map of seismic time it is intended to show the structure of a horizon in the subsurface. Obviously it does not show the structure directly. Structure is matter of depth and the map is travel time of sound waves. To make a map that is more truly related to the subsurface, depths must be calculated from the times. Here we need truly velocities. So with the help of formula given below, we can convert the Seismic Time Section into Seismic Depth Section.

Depth=Average Velocity * Time

But the velocity determined from the seismic data is not accurate and the deeper it is, the poorer it is. So problems will arise when the maps of the depth tie with the wells. This is why most of the maps are made in seismic reflection time. But the velocity pull up and pull down makes the time structure in correct below the feature that is why it is some times essential to make the depth section along with the time maps. Depth Section of line 856-SGR-58 is shown in Fig:4.13 and for 846-SGR-50 is shown in Fig: 4.14. Both Depth Section shows Horst and Graben structures.

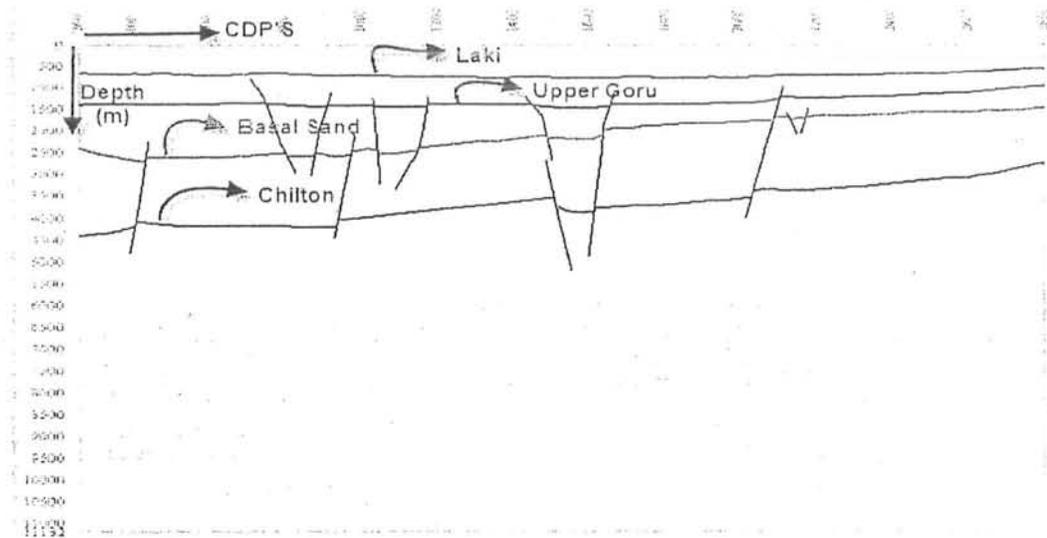

Fig:4.13 Seismic Depth Section for line 856-SGR-58

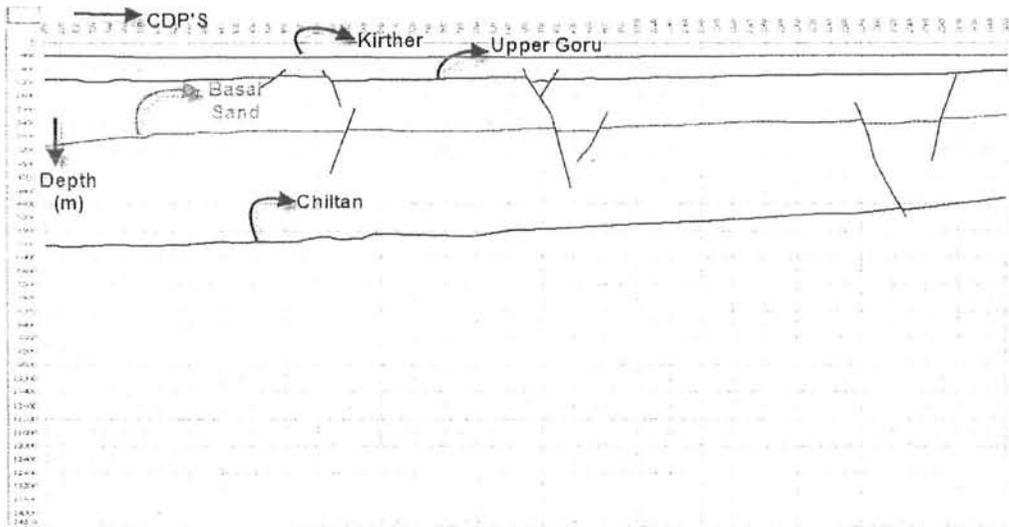

Fig:4.14 Seismic Depth Section for line 846-SGR-50

4.6.1 CONTOUR MAPS

Contouring is the main tool used in industries for delineating the subsurface structures from the interpreted seismic data. On the basis of this contouring wells are proposed. After contouring it becomes obvious that what sort of structure is forming a particular horizon. Basal sand is selected for the purpose of constructing contour maps because they act as good reservoirs in the present study area.

4.6.2 TIME CONTOUR MAP OF BASAL SAND

After the marking of horizons at different levels, the next step is to contour the area at a particular level and prepare its surface. Here the data of six lines are used for contouring which includes 856-SGR-58, 856-SGR-67, 856-SGR-53, 846-SGR-45, 846-SGR-50, 856-SGR-59. One of these three are dip lines and three are strike lines. Using the 'SURFER' the contour maps are prepared. Where contours are closely spaced they show abrupt change in time to the Formations. The time contour map of Basal Sand is shown in the Fig :4.15

Where the contour lines in maps are closely spaced, they represent the steeper slope of the structure and where the lines are largely spaced, they represent gentle slope of the structures.

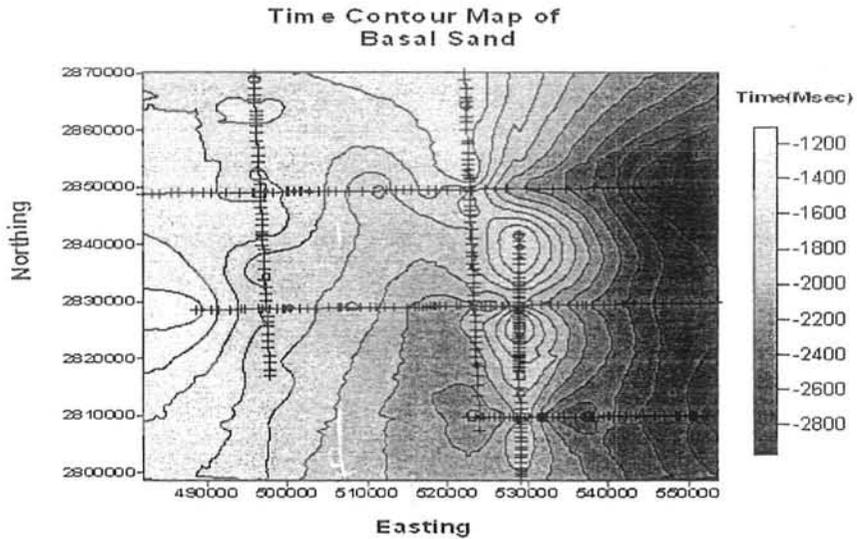

Fig:4.15 Time Contour Map of Basal Sand

4.6.3 DEPTH CONTOUR MAP OF BASAL SAND

By using the same data that is used for the time contour mapping and the velocities additionally velocity functions are used for Depth Contour Map. It shows normal faults.

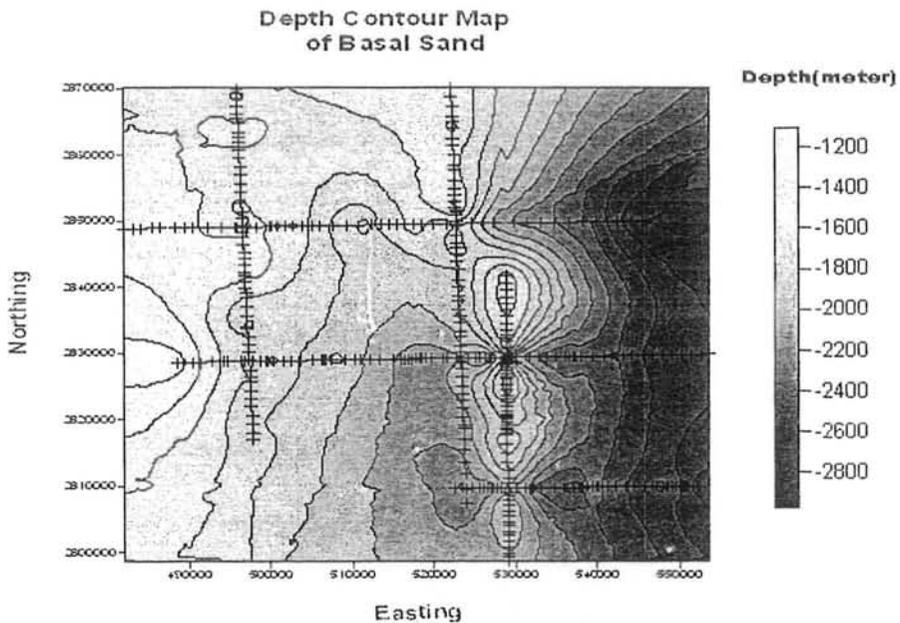

Fig:4.16 Depth Contour Map of Basal Sand

4.7.1 TIME SURFACE MAP OF BASAL SAND

The next step is to make the surface at that level.. The 3D time surface map of Basal Sand is shown in Fig 4.17. It shows many EW trending Horst and Graben Structures. These structures may be suitable for hydrocarbon accumulation.

4.7.2 DEPTH CONTOUR MAP OF BASAL SAND

By using the same data that is used for the time contour mapping and the velocities additionally from the velocity functions. Depth contour map of Basal Sand is shown in the Fig 4.18. It shows many EW trending Horst and Graben Structures.

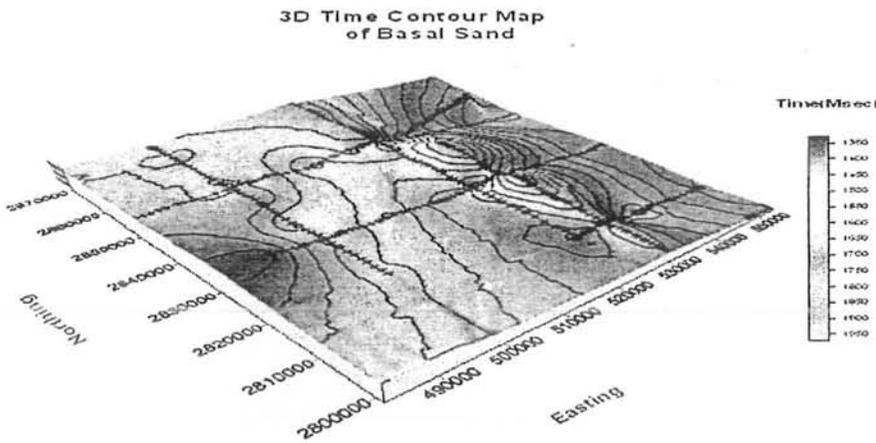

Fig:4.17 3D Time contour Map of Basal Sand

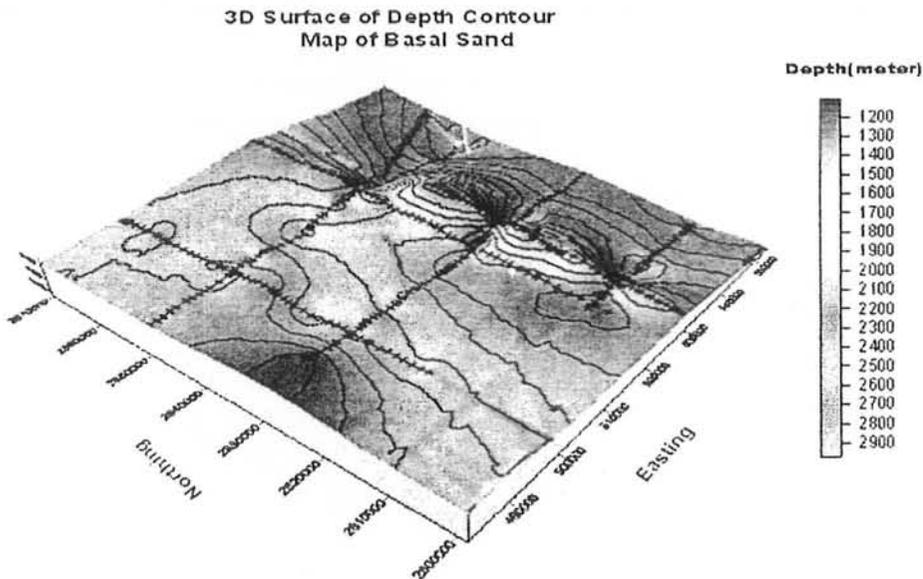

Fig:4.18 3D Depth contour Map of Basal Sand

4.8 ROCK PHYSICS ANALYSIS OF LOWER GORU

Through rock physics analysis we can describe the behavior of a rock unit by analyzing its physical properties such as porosity, rigidity, compressibility & density etc. It also shows that how seismic waves physically behave when they propagate through the earth materials. This analysis has been made for a zone (LOWER GORU) whose depth ranges from 2000m to 2900m. Actually this analysis is made by plotting the cross products of certain physical properties from different logs in order to seek for the existence of some potential zones.

4.9 CALCULATION OF PARAMETERS AND THE ZONE OF INTEREST

The rock parameters which were used in calculation of following graphs are briefly described below:

ρ = Density

K = Bulk Modulus

μ = Shear Modulus

σ = Poisson Ratio

Vp/Vs = Vp/Vs Ratio

All these parameters are shown in Appendix#1

4.9.1 DENSITY DETERMINATION

Density is a major property of rock which describes the amount of solid part of the rock body per unit volume. Direct estimation of density from seismic velocities have been done by using the formula

$$\rho = 0.31 * (Vp)^{0.25}$$

Where ρ = Density, Vp = P-Wave Velocity in m/sec

Density is used in various moduli Calculation.

Density Vs Depth graph is shown in Fig:4.19 this graph show abrupt change in density from depth 2100-2500m. As reservoir is characterised by low density.

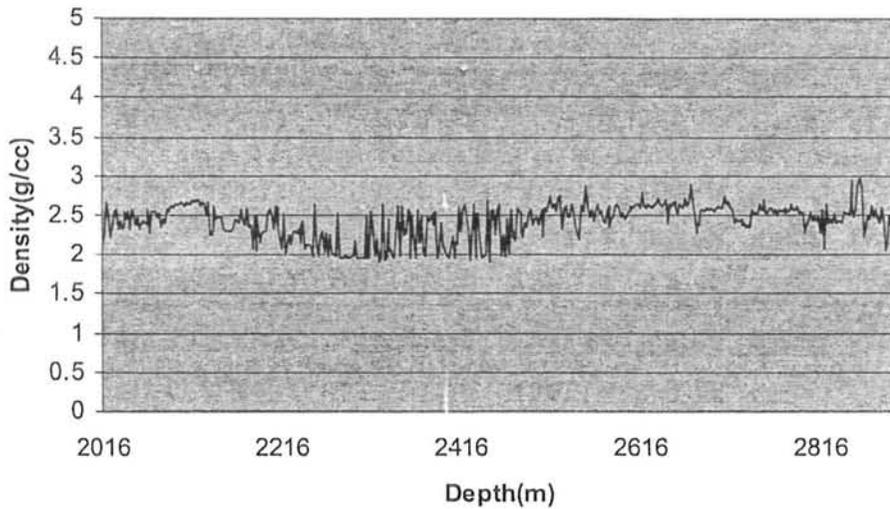

Fig: 4.19 Density Vs Depth

4.9.2 P-WAVE VELOCITY Vs POROSITY OF LOWER GORU

As reservoir is marked by lower P-Wave Velocity with high Porosity Fig.4.20 shows that low velocity are marked by high Porosity, which is favourable for accumulation of hydrocarbon.

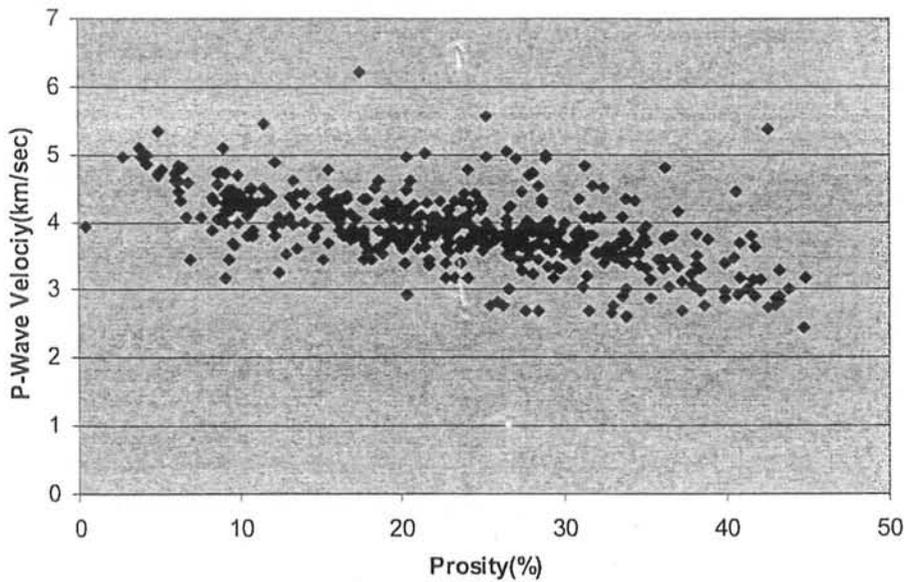

Fig 4.20 Porosity Vs P-Wwave Velocity

4.9.3 THE BULK MODULUS

It is the measure of how much a rock is compressed when seismic waves propagate through it. It is also known as the modulus of compressibility. Certainly different rock types have different values of compressibility due to their porosity, density, mineralogy, grain racking and fluid contents. Estimation of bulk modulus from seismic velocity and density have been done by using formula:

$$K = (V_p^2 - 1.333 * V_s^2) * \rho$$

Where K = Bulk Modulus, ρ = Density, V_p = P-Wave Velocity

Reservoir rock is characterised by low Bulk Modulus. Fig 4.21 shows that Bulk modulus values are low from the depth 2100-2350m and 2460-2700m, but these have high shale content.

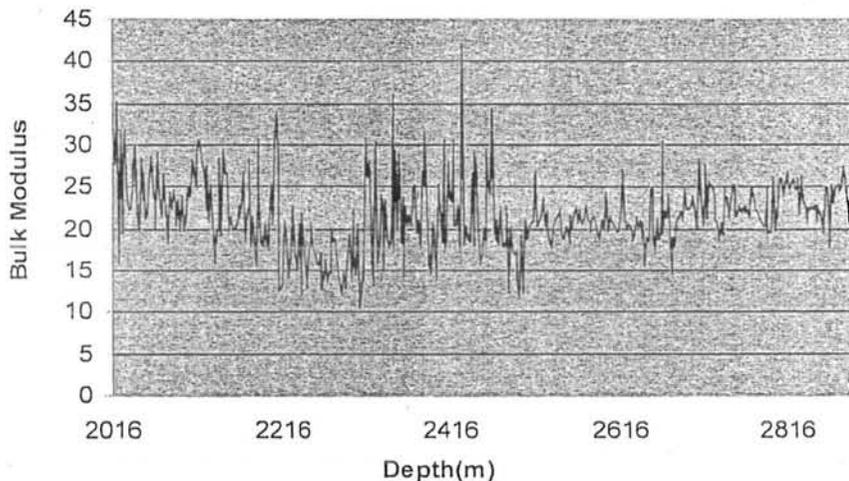

Fig 4.21 Bulk Modulus Vs Depth

4.9.4 THE SHEAR MODULUS

Shear waves are more anomalous than compressional waves. But in the case of fluids present in rocks, P-Waves become more anomalous than S-waves because S-waves cannot pass through fluids and only pass through rock units. But P-Waves pass through both rock and fluid and hence more anomalous.

Estimation of Shear Modulus from shear wave velocity and density have been done by using the formula

$$\mu = \rho * V_s^2$$

Where μ = Shear Modulus

Reservoir rock is characterised by low Shear Modulus Fig 4.22 shows that Shear modulus values are low from the depth 2100-2350m and 2460-2700m , but from 2200-2350m and 2460-2700m, volume of shale is high.

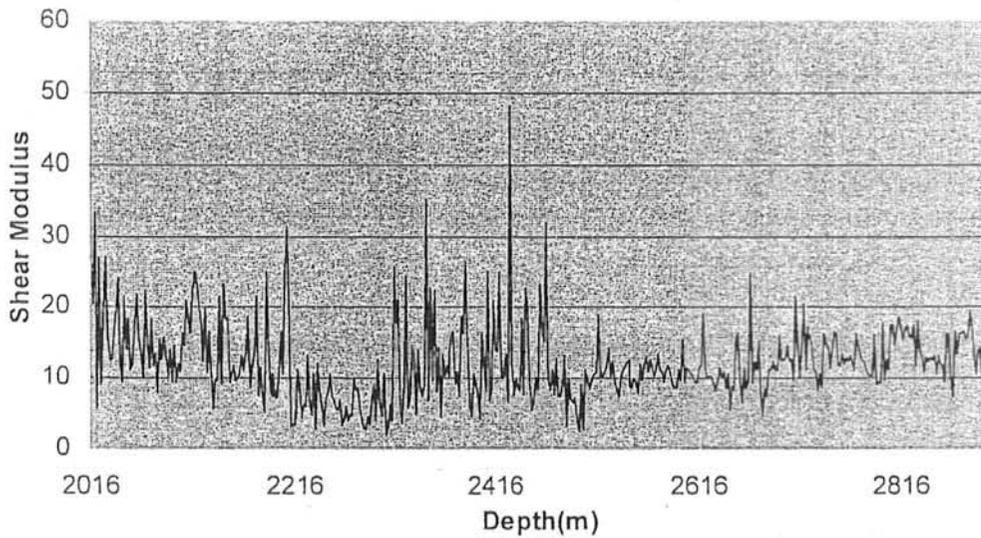

Fig.4.22 Shear Modulus Vs Depth

4.9.5 POISSON RATIO Vs POROSITY

Fig 4.23 shows that Poisson Ratio increases with increasing porosity.

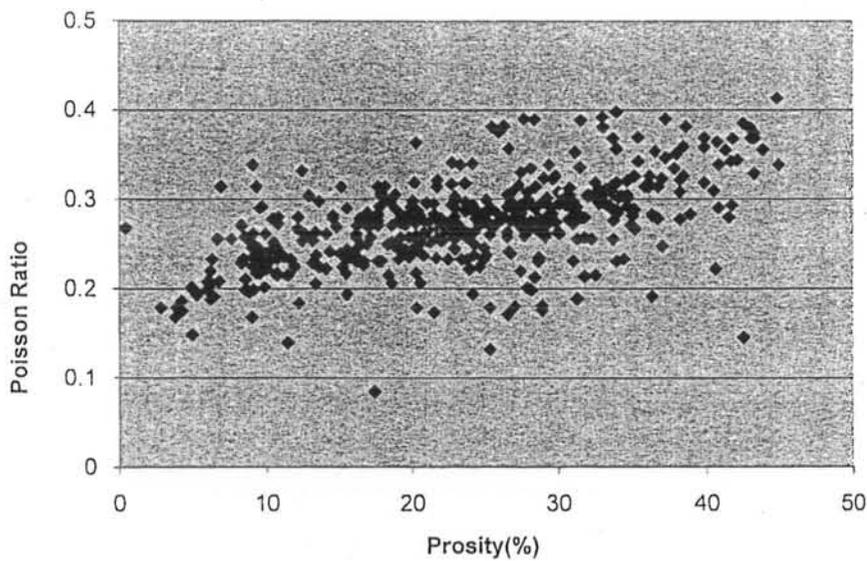

Fig 4.23 Poisson Ratio Vs Porosity.

4.9.6 THE POISSON RATIO

Poisson's Ratio is defined as the transverse strain divided by longitudinal strain. This means that it is the measure of incompressibility of the rock body. Poisson ratio is more dependent on P-Wave velocity rather than S-wave velocity.

Poisson ratio is calculated by using the formula:

$$\sigma = ((0.5 * (V_p^2 - 2V_s^2) / (V_p^2 - V_s^2)) \text{ Khan, et al. (2010)}$$

In other words we can say that the Poisson ratio is the measure of the behavior of seismic waves when they pass through the rock body. Reservoir is marked by high Poisson's Ratio. Fig 4.24 shows that Poisson Ratio is high from the depth 2200-2350m and 2460-2650m, This zone have high shale content. From depth 2016-2200m and 2650-2900m Poisson's Ratio round about 0.25.

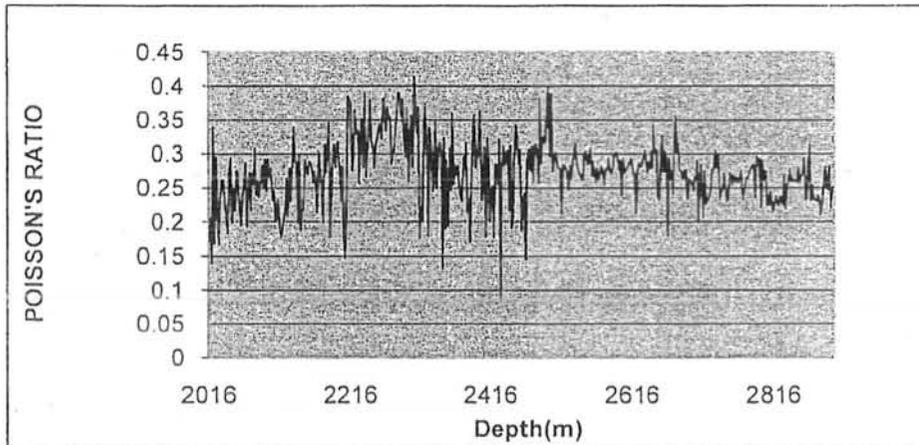

Fig 4.24 Poisson Ratio Vs Depth

4.9.7 P-WAVE AND S-WAVE IMPEDENCE Vs DEPTH

Reservoir rock is characterised by low both P-Wave and S-Wave Impedance are low. Fig 4.25 shows low impedences from the depth 2100-2400m and 2460-2700m, but these zones have high shale content.

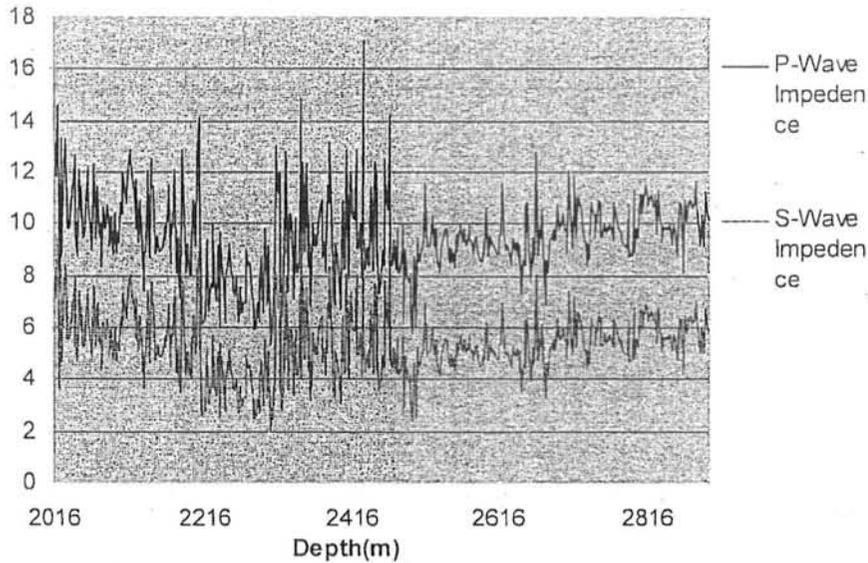

Fig 4.25 P-Wave and S-Wave Impedence Vs Deapth

PETROPHYSICAL ANALYSIS

4.10.1 VOLUME OF SHALE

Shale has high Porosity, so separation of shale from reservoir unit is necessary, and it is more difficult task when small beds of sands are present in reservoir unit. In lower Goru there are thin beds of sand are present.

Three zone are encircled from remaining unit on the basis of volume of shale, from depth 2016-2176m, 2716-2730m and 2808-2838m as shown in Fig.4.26

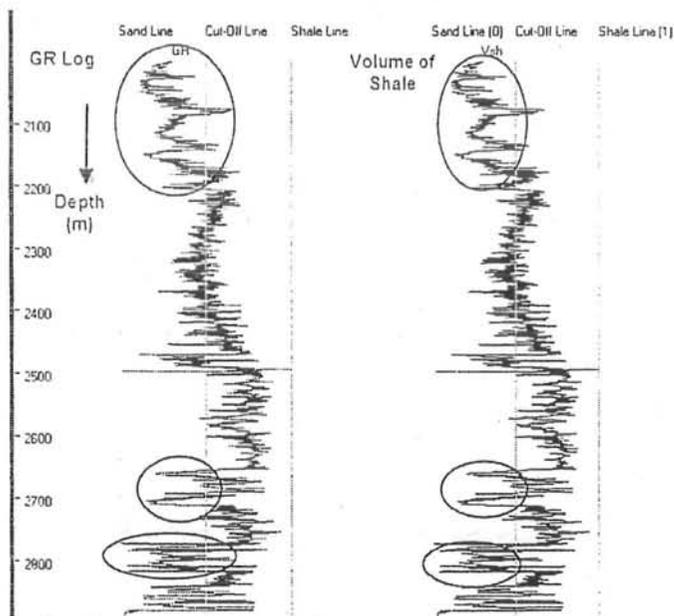

Fig: 4.26 Depth Vs Volume of shale

This graph is generated using Wavelet software. K-Tron, et al. (2010)

Volume of shale is estimated from Gamma Ray Log and is calculated by equation as given below:

$$V_{sh} = \frac{(GR_{log} - GR_{min})}{(GR_{max} - GR_{min})}$$

V_{sh} = Volume of shale

GR_{log} = Value from GR Log

GR_{min} = Minimum value of GR

GR_{max} = Maximum value of GR

The result of volume of shale is shown in Appendix#1. Average Volume of shale in encircled zones is 26%. and it is suitable for reservoir unit.

4.10.2 THE POROSITY Vs DEPTH

Porosity is the percentage of voids to the volume of rock. NPHI Log is used for petrophysical analysis. It is very important parameter for reservoir, more than 15% Porosity is good for reservoir rock. Porosity Vs Depth Graph is shown in Fig:4.27

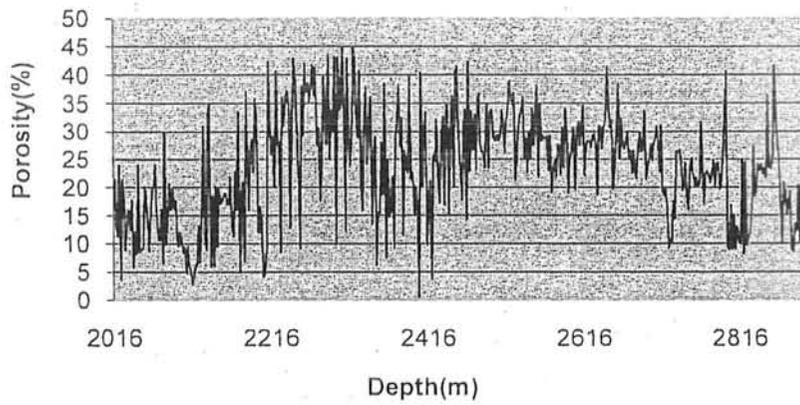

Fig: 4.27 Porosity Vs Depth

Fig 4.27 shows that from depth 2200-2400m and 2460-2700m Porosity is high but these zones have high shale content.

CONCLUSIONS

Four Reflectors were marked for both lines according to stratigraphic column of the area.

- Kirther
- Upper Goru
- Basal Sand
- Chiltan

Interpreted seismic Section shows Horst and Graben structures which may be favourable for hydrocarbon accumulation. Time and Depth Surface Contour Map also prepared which shows Horst and Graban.

Rock Physics Analysis of Lower Goru shows that there is no potential zone exist. For reservoir these properties (P -Wave and S-Wave Velocity, P-Wave and S-Wave Impedence, Shear and Bulk Modulus) must be low in reservoir, but these are high in Sand, so probably there is no reservoir zone exist.
